# Gait and Cognitive Functions

Essay Submitted for Partial Fulfillment of the Requirement of the  
Master Degree in Neurology and Psychiatry

By

**Ayman Tafid Ali Mohamed Gawish**

MB. BCh – Alexandria University

Supervised by

**Prof. Hany Mohamed Amin Aref**

Professor of Neurology and Psychiatry

Ain Shams University

**Dr. Lobna M. El Nabil El Sayed**

Assistant Professor of Neurology and Psychiatry

Ain Shams University

**Dr. Pousette Farouk Gaber**

Lecturer of Neurology and Psychiatry

Ain Shams University

Faculty of Medicine

Ain Shams University

2013

# المشية والوظائف المعرفية

رسالة

توطئة للحصول على درجة الماجستير في أمراض المخ والأعصاب والطب النفسي

مقدمة من

الطبيب / أيمن تفيد على محمد جاويش

بكالوريوس الطب والجراحة - جامعة الإسكندرية

تحت إشراف

أ. د. هانى محمد أمين عارف

أستاذ أمراض المخ والأعصاب والطب النفسي

كلية الطب - جامعة عين شمس

د. لبنى محمد النبيل السيد

أستاذ مساعد أمراض المخ والأعصاب والطب النفسي

كلية الطب - جامعة عين شمس

د. بوسيت فاروق جابر

مدرس أمراض المخ والأعصاب والطب النفسي

كلية الطب - جامعة عين شمس

كلية الطب

جامعة عين شمس

2013

بِسْمِ اللَّهِ الرَّحْمَنِ الرَّحِيمِ

وَأَنْزَلَ اللَّهُ  
عَلَيْكَ الْكِتَابَ  
وَالْحِكْمَةَ  
وَعَلَّمَكَ مَا لَمْ  
تَكُنْ تَعْلَمُ  
وَكَانَ فَضْلُ  
اللَّهِ عَلَيْكَ  
عَظِيمًا

This work is dedicated to ...

My beloved Parents, to whom I owe everything I ever did in my life and will achieve

My beloved wife and my lovely daughter  
(**Roqaya**) for being the light of my life

## Acknowledgment

---

### Acknowledgment

**F**irst and before all I thank Allah . I thank him for his great mercy, generous blesses, and for his continuous gifts. I thank him for giving me the ability to achieve this work.

I would like to thank **Prof. Hany Mohamed Amin Aref** Professor of Neurology, Faculty of medicine, Ain Shams University, who had the idea of this interesting topic. He gave me much of his time, experience, meticulous constructive advice and support. His fatherhood attitude, patience, encouragement were indispensable for completion of this work.

I am very grateful to **Prof. Dr. Lobna M. El Nabil El Sayed** Professor of Neurology, Faculty of medicine, Ain Shams University, for her kind supervision, support, indispensable suggestion and great help throughout the course of this work.

Words can never express my sincere thanks to **Dr. Pousette Farouk Gaber** lecturer of Neurology, Faculty of medicine, Ain Shams University, for her continuous encouragement, enthusiastic support indispensable suggestion and great help throughout the course of this work.

---

# INTRODUCTION

The relationship between higher-level cognitive function and gait disturbances has received considerable attention in recent years (**Yogev et al., 2008**). Until recently gait has been considered as an automated motor activity independent from cognitive function. However, recent arguments suggest a strong link between gait and cognition, in particular in neurodegenerative disorders such as Alzheimer's disease and related disorders. Executive functions seem to play a central role in these gait disorders due to deficits in cognition (**Allali et al., 2010**).

Gait is a learned, complex and almost automatic task with limited involvement of cognitive control in healthy individuals until the onset of old age. Previous studies have established the importance of cognitive control on gait in older adults; gait slowing is more prevalent in people with cognitive impairment and slow gait in healthy older adults is associated with a higher risk of cognitive impairment, including dementia (**Holtzer et al., 2006**). A slow gait velocity has been associated with an increased risk of falls, hospitalization and mortality (**Verghese et al., 2010**).

## Introduction

---

Changes in cognitive functions contribute to changes in the variability and stability of the gait pattern. Walking under dual task conditions and quantifying gait using dynamical parameters can improve detecting walking disorders and might help to identify those elderly who are able to adapt walking ability and those who are not and thus are at greater risk for falling (**Lamoth et al., 2011**). Managing gait disorders at early stages can help prevent further deconditioning and mobility impairment (**Lam, 2011**).

Previous findings underscore the fact that gait and complex cognitive functioning are closely related. Gait should no longer be considered a simple automatic motor activity that is independent of cognition; it should be treated as a higher level of cognitive functioning (**Hausdorff et al., 2005**).

The executive functions (EF) integrates cognitive and behavioral components necessary for effective, goal-directed actions and for the control of intentional resources thus enabling the human being to manage independent daily activities (**Stuss and Levine, 2002**). White matter hyper-intensities on magnetic resonance imaging were associated with a decline of EF, but not with the level of general intelligence (**Gunning-Dixon and Raz, 2003**).

## Introduction

---

Loss of dendritic branching in the prefrontal cortex is also associated with a decline in performance on EF tests. Age-associated decline in dopaminergic Activity in the frontal areas is also related to poorer performance on executive tasks (**Burke and Barnes, 2006**) Impairment of one or more of EF components reduces the ability to walk efficiently and safely (**Yogev-Seligman et al., 2008**) For example, poor self-awareness of limitations, an aspect of impaired volition, increases the risk of falling in elderly patients with dementia (**Van Iersel et al., 2006**). In older adults with mild cognitive impairment (MCI), low working memory performance was associated with slow gait velocity (GV). Dual-task conditions showed the strongest associations with gait slowing. The findings suggest that cortical control of gait is associated with decline in working memory in people with MCI (**Montero-Odasso et al., 2009a**).

The contribution of cognition to gait is particularly evident in patient with Parkinson's disease (PD) with gait disorders who have a reduced ability to perform multiple tasks simultaneously, either because the central processing abilities have become too limited, or because patients fail to properly prioritize their balance control over other less important tasks (**Yogev-Seligman et al., 2008**). While there

## Introduction

---

have been several studies of comprehensive, multidisciplinary rehabilitation programs for individuals with PD, none have included any cognitive assessments nor interventions aimed at cognitive rehabilitation (**Wade et al., 2003**). Therefore, studies in Alzheimer's disease must be examined to explore the potential of cognitive therapy and its possible application in Parkinson's disease patients (**Loewenstein et al., 2004**).

Gait disorders are more prevalent in dementia than in normal aging and are related to the severity of cognitive decline. Dementia-related gait changes (DRGC) mainly include decrease in walking speed provoked by a decrease in stride length and an increase in support phase. More recently, dual-task related changes in gait were found in Alzheimer's disease (AD) and non-Alzheimer dementia, even at an early stage (**Beauchet et al., 2008**). Predicting and anticipating disturbances in higher level gait is particularly relevant for patients with dementia as higher level gait appears to be closely related to higher level cognitive functioning (**Scherder et al., 2011**). Decreased executive function plays an important role in increased gait variability in dementia patients; a fact that should be considered when designing fall risk interventions for this population. Furthermore, results indicate that measures of
