صدق الله العظيم

سورة البقرة
الآية ٣٢

To My Dear Family:
My Father, My Mother, My Brother,
My Husband and My Lovable Daughters

ACKNOWLEDGEMENT

I would like to express my deep gratitude and appreciation to Dr. KARIMA ABDEL KHALIK, Professor of Paediatrics, Faculty of Medicine, Ain Shams University, for giving me the honour of working under her supervision, for her encouragement, and her invaluable remarks and suggestions.

To her I am delighted to acknowledge my indebtedness.

AMIRA M. ABDEL-ALL
1987

LIST OF ABBREVIATIONS

Hb	: Haemoglobin
α	: Alpha
β	: Beta
γ	: Gamma
δ	: Delta
ϵ	: Epsilon
ζ	: Zeta
RBC	: Reticulocytic blood corpuscle
Thal.	: Thalassaemia

LIST OF CONTENTS

■ Introduction	1
■ Structure of Normal Haemoglobins	7
■ Genetic Control of Haemoglobin Synthesis	11
■ Haemoglobin Synthesis	12

LIST OF TABLES

Table 1:	New abnormal haemoglobins	5
Table 2:	Primary structure of α and β globin subunits	11
Table 3:	Abnormal foetal haemoglobin	20
Table 4:	Different variants of unstable haemoglobins	53
Table 5:	The main types of β thalassaemias	82
Table 6:	Clinical and laboratory findings in β thalassaemia	83
Table 7:	The main groups of disorders of δ and β chain production	89
Table 8:	The Alpha-thalassaemia syndromes	93
Table 9:	Classification of α thalassaemia syndromes	94

LIST OF FIGURES

- Fig. 1: The sequence of amino acid residues in the α chain of haemoglobin.
- Fig. 2: The sequence of amino acid residues in the β chain of haemoglobin.
- Fig. 3: Structure of haeme.
- Fig. 4: The amounts of α , β , γ , δ , ϵ , and ζ chains at different times in the development of the human embryo, infant.
- Fig. 5: The mechanism of polypeptide chain biosynthesis.
- Fig. 6: Relative electrophoretic mobility of human haemoglobins on starch gel.
- Fig. 7: The oxygen dissociation curve of human haemoglobin.
- Fig. 8: The genetics of the thalassaemias.
- Fig. 9: Diagram of uterus at 9 week's gestation, with biopsy catheter.
- Fig. 10: Genotyping DNA samples by hybridization with oligonucleotides.

INTRODUCTION

INTRODUCTION

Haemoglobin has been described once by the American biochemist L.J. Henderson as "The second most interesting substance in the world (*Barcroft, 1928*).

In the eighteenth and nineteenth centuries, the ideas about the importance of oxygen for life, and the production of animal heat by controlled combustion or respiration developed slowly. It was not shown until 1864 by the English mathematician and physicist *George Stokes* that haemoglobin, reversibly binds and releases oxygen, changing colour as it does so. It was one of the first proteins to be purified to the point where its molecular weight and amino acid composition could be established accurately (*Dickerson and Gleis, 1983*).

The main role of Hb is to bind molecular O₂ to its haem irons at the lungs and to deliver it to the tissues. A second task is to bring the CO₂, by product of oxidation to the lungs to get rid of it (*Stryer, 1981*).

The concentration of Hb within human red cells is high (34 gm/dl) and its efficiency as an oxygen carrier is enhanced by its packaging in flexible (red) cells of optimal shape for the diffusion of gases (*Bunn et al., 1977*).

The molecular and biochemical characteristics of the haemoglobins are remarkably well known now. The genes of

their component polypeptide chains have been located on chromosomes number 11, 16 and the actual genes have been isolated and their DNA sequences determined (*Nelson, 1983*).

The Alpha Chains

A pair of polypeptide chains present in each molecule of all haemoglobin variants in the normal human blood.

Each chain contains 141 aminoacids. It has an N-terminal sequence, valine-leucine. The amino acid sequence of alpha polypeptide chain is shown in Fig. (1).

The Non Alpha Chains

There are 3 types of non alpha chains in normal human blood: Beta (β), gamma (γ) and delta (δ).

The β Chain

A pair of β polypeptide chains are normally present in each molecule of the major adult Hb A₁. Each β chain contains 146 amino acids. The β chain has an N-terminal sequence Valine-Histidine. The amino acid sequence of β polypeptide chain is shown in Fig. (2).

The Delta Chain

Each molecule of the minor adult component HbA₂, contains a pair of delta chain besides the pair of alpha chain. Each delta chain contains 202 amino acids residues and differs from β chain and γ chain.

ig. 2: The sequence of 146 amino acid residues in the β chain of haemoglobin From Murayama (1971).

The Gamma Chain

Each molecule of foetal Hb contains a pair of gamma chain. Each gamma chain contains 146 aminoacids, the same number as the β chains (*Jukes, 1966*).

During the last 20 years, knowledge of molecular defects underlying the group of haematologic disorders called haemoglobinopathies has burgeoned at tremendous pace. Techniques for peptide and amino acid analysis, following enzymatic degradation of the large haemoglobin polypeptide chains, have led to the discovery of 154 variants due to a single point mutations in the α chain.

In the β chain, 250 due to a single point mutation and 4 with 2 point mutations. Ten due to point mutations in the δ chain, and 19 due to point mutations in the γ chains (*Virgil, 1983*).

Most haemoglobin variants have no clinical effect, even though they may be found to have some malfunction when scrutinized in the research laboratory. Most patients in whom they are detected are heterozygotes. Homozygotes may have abnormal red cell morphology without anaemia. Unstable variants, those with high or low oxygen affinity or those causing methaemoglobinaemia, are expressed in heterozygotes, and there is always the chance of a double heterozygote for an abnormal haemoglobin and thalassaemia.

HbS and rare sickling variants are unique in that they are relatively harmless in the heterozygote but may produce a severe disease in the homozygote and in some double heterozygotes such as Hb S/C, S/O Arab and S/D Panjab (*Bunn et al., 1977*).

Several new substitutions have been discovered in the past few years and are listed in table (1) (*Chalaby et al., 1985*).

AIM OF THE ESSAY

Review of the haemoglobinopathies in newborn including:

1. Genetic control of haemoglobin synthesis.
2. Normal human haemoglobins.
3. The different haemoglobin variants and haemoglobinopathies.
4. Prenatal diagnosis and neonatal screening for haemoglobinopathies.

Table 1: New Abnormal Haemoglobins

Residue	Substitution	Name	Electrophoretic Mobility pH 8.4	Clinical Effect
α chain				
$\alpha 6(A4)$	Asp-deleted	Hb Boyle Heights	Between Hb f&5	None
$\alpha 6(A4)$	Asp-Val	Hb Ferndown	Behind Hb A	None
$\alpha 11(A9)$	Lys-Cln	Hb J-Wenchang-Wuming	In front of Hb A	None
$\alpha 20(B1)$	His-Tyr	Hb Necker Enfants Malades	Like Hb A ^o	None
$\alpha 27 (B8)$	Glu-Lys	Hb Shuangfeng	In front of Hb A ₂	Haemolytic anaemia
$\alpha 44(CE2)$	Pro-Arg	Hb Kawachi	Like Hb A	Erythrocytosis
$\alpha 45(CE3)$	His-Gln	Hb Bari	Like Hb A	None
$\alpha 49(CE7)$	Ser-Arg	Hb Savaria	Like Hb S	None
$\alpha 56(E5)$	Lys-Glu	Hb Shaare Zedek	Like Hb H	None
$\alpha 60(E9)$	Lys-Glu	Hb Dagestan	Like Hb I	None
$\alpha 75(EF4)$	Asp-Gly	Hb Mizushi	Like Hb S	None
$\alpha 8(F2)$	Ser-Cys	Hb Migeria	Like Hb A ⁻	α -Thalassaemia trail
$\alpha 8(F8)$	His-Arg	Hb M-Iwate	Behind Hb A	Mathaemo-globinemia
$\alpha 122(H5)$	His-Gln	Hb Westmead	Like Hb A	α -thalassaemia trail
$\alpha 125(H8)$	Leu-Pro	Hb Quong Sze	Like Hb A	α -Thalassaemia trail
β chain				
$\beta 13(A10)$	Asp-Asp	Hb J-Lene	Like Hb 3	None
$\beta 21(B3)$	Asp-Asn	Hb Cocody	Like Hb S	None
$\beta 21(B3)$	Asp-Tyr	Hb Connecticut	?	Low O ₂ affinity
$\beta 21(B3)$	Asp-Tyr	Hb Yusa	Like Hb S	None
$\beta 23(B5)$	Val-Cly	Hb Miyashiro	Like Hb A	None
$\beta 31(B13)$	Leu-pro	Hb Yokohama	Like Hb A	Compensated haemolytic anaemia
$\beta 34(B16)$	Val-Phs	Hb Pitie-Salatriere	Like Hb A ^o	Erythrocytosis
$\beta 45(CD4)$	Pha-Ser	Hb Cheveriy	Like Hb A	Erythrocytosis cyanosis
$\beta 52(D3)$	Asp-His	Hb Summer Hill	Like Hb S	None
$\beta 75(E19)$	Leu-Arg	Hb Pasadena	Like Hb S	Compensated haemolytic anaemia
$\beta 75(E19)$	Leu-deleted	Hb Vickaburg	Like Hb A	β -Thalassaemia
$\beta 79(EF3)$	Asp-Tyr	Hb Tampa	Between Hb F and S	Normal homo- and Heterozygotes
