

**Growth Differentiation Factor 15  
Expression in Anemia of Chronic  
Disease and Iron Deficiency  
Anemia**

*Thesis*

Submitted for partial fulfillment of Master Degree  
in Clinical & Chemical Pathology

*By*

**Rana El-Said Ali El-Nashar**

M.B., B.Ch.

Ain Shams University (2008)

*Under Supervision of*

**Prof. Dr. Hala Mahmoud Hamdy Abaza**

Professor of Clinical Hematology

Faculty of Medicine – Ain Shams University

**Dr. Deena Mohamed Mohamed Habashy**

Lecturer of Clinical & Chemical Pathology

Faculty of Medicine – Ain Shams University

**Faculty of Medicine**

**Ain Shams University**

**2012**

وَأَنْزَلَ اللَّهُ عَلَيْكَ  
الْكِتَابَ وَالْحِكْمَةَ  
وَعَلَّمَكَ مَا لَمْ تَكُنْ  
تَعْلَمُ وَكَانَ فَضْلُ  
اللَّهِ عَلَيْكَ عَظِيمًا

صدق الله العظيم

سورة النساء الآية (١١٣)

## Acknowledgement

*First and foremost, I feel always indebted to Allah, the most kind and the most merciful.*

*I would like to express my sincere gratitude to Prof. Dr. Hala Mahmoud Hamdy Abaza, Professor of Clinical Hematology, Faculty of Medicine – Ain Shams University. Under her supervision, I had the honor to complete this work, I am deeply grateful to her for her professional advice, guidance and support.*

*I wish also to express my gratitude to Dr. Deena Mohamed Mohamed Habashy, Lecturer of Clinical & Chemical Pathology, Faculty of Medicine – Ain Shams University, for her great efforts, kind advice, support and encouragement throughout the whole work.*

**Rana EL-Nashar**

*I would like to dedicate this Thesis to my **Family**,  
to them I will never find adequate words  
to express my gratitude.*

*Also to my Fiancé for behaving tactfully  
and patiently during this work*

## Introduction

**G**rowth differentiation factor 15 "GDF 15" is a divergent member of the transforming growth factor-B superfamily. It has been identified as a hypoxia-inducible gene product and as a molecule involved in hepcidin regulation (*Lakhal et al., 2009*). The "GDF 15" expression during late erythroid differentiation was discovered as part of an erythroblast transcriptome project (*Tanno et al., 2010<sub>a</sub>*). Although "GDF 15" expression is associated with cellular stress or apoptosis, this hormone is a prerequisite for normal erythroid differentiation (*Lakhal et al., 2009*).

The "GDF 15" is involved in ineffective erythropoiesis (*Tanno et al., 2010<sub>a</sub>*) being strongly increased in B-thalassaemia and congenital dyserythropoietic anemia. The cytokine blocks hepcidin expression and increases iron absorption, thus, leading to iron loading in these anemias (*Tamary et al., 2008*). In contrast, mildly increased "GDF 15" concentrations do not suppress hepcidin expression, as seen in-vitro and in patients with other types of iron-loading anemias (e.g., sickle cell anemia, myelodysplastic syndrome or pyruvate kinase deficiency) (*Finkenstedt et al., 2009*).

Since intracellular iron availability affects "GDF 15" expression (*Lakhal et al., 2009*), recent studies are investigating the potential pathophysiological role of "GDF 15" in anemia of

chronic disease (ACD) and iron deficiency anemia (IDA). Moreover, detection of the association of "GDF 15" expression with serum iron parameters in patients suffering from IDA and ACD may be helpful to assess the diagnostic and pathogenic impact of "GDF 15" in these anemias (*Theurl et al., 2009*).

Anemia of chronic disease is a common clinical problem complicating diseases involving acute and chronic immune activation, such as infections, malignancies or autoimmune disorders (*Weiss and Goodnough, 2005*). The circulating concentrations of the "GDF 15" are significantly increased in ACD, most likely as a consequence of inflammation with yet not elucidated pathophysiological roles (*Theurl et al., 2009*).

Iron deficiency anemia affects billions of persons worldwide. It develops when iron stores become insufficient to maintain normal erythropoiesis (*Tanno et al., 2010<sub>b</sub>*). Iron depletion increases "GDF15" expression in cultured cells, and iron chelation causes a transient increase of "GDF 15" levels among human research subjects. Significant elevation of "GDF 15" was found among randomly chosen patients with ID, but other etiologies for increased "GDF 15" were not explored (*Lakhal et al., 2009*). Although "GDF 15" is probably linked to the degree of anemia and the need for erythropoiesis and iron homeostasis in IDA, the role of "GDF 15" in IDA is still controversial (*Theurl et al., 2009*).

Human "GDF 15" protein level in cell supernatants and human sera is measured by Enzyme-linked immunosorbent assay (ELISA) or immunoradiometric assay. The ELISA is a sensitive, specific, quantitative and reliable technique, with relatively stable reagents. Moreover, it is quick, convenient, generally safe (no radioactive decay) (*Harvey and Champe, 2008*) and is used in a wide variety of laboratories.

## **Aim of the work**

The aim of the present study is:

- Detection of GDF 15 expression in Egyptian patients with IDA and ACD.
- Comparison between GDF 15 level in IDA, ACD and healthy subjects.
- Correlation between GDF 15 level, iron profile and degree of anemia in both IDA and ACD.

## **Iron Metabolism**

### ***Body Iron:***

Iron is critical to human life and important for growth. It plays the central role in the formation of hemoglobin, brain development and function, and muscle activity. Iron also functions in several key enzymes in energy production and metabolism including DNA synthesis (*Wrighting and Andrews, 2008*).

Approximately 73% of body iron is normally incorporated into hemoglobin and 12% in the storage complexes "ferritin and hemosiderin". The remaining iron 15% is of great importance as it is incorporated into a variety of other iron-containing compounds of vital functions. Therefore, body iron can be considered as having two main components: functional iron and stoage iron (*Anderson et al., 2009*).

The functional component of iron is found largely in the circulating hemoglobin and smaller quantity in body tissue, myoglobin and enzymes. A deficiency of iron in the functional component does not ordinarily occur until stores are completely exhausted. The storage component "ferritin and hemosiderin" in the liver and bone marrow, serves as source for functional component (*Mun~oz et al., 2009*).

Iron is required for the production of hemoglobin. One molecule consists of protein "globin" combined with four
