Acknowledgement

My great thanks and gratitude to **Allah** , for all gifts given to me, and whose help I always seek to put my feet in the right road.

I wish to express my sincere gratitude to **Professor Dr. Saad Aly Abd Rabu**, for his encouragement and constant advice.

I owe special gratitude to **Dr. Mohamed Sobhi Hassan**, for bearing with me and for his constant encouragement and most valuable advice throughout the execution of this work.

I would like to thank my professors for their support and inspiration.

Last but not least, sincere gratitude to *My Parents* your prayers are what sustains me.

بِسْمِ اللَّهِ الرَّحْمَنِ الرَّحِيمِ

قالوا

لسبحانك لا علم لنا
إلا ما علمتنا إنك أنت
العليم العظيم

صدق الله العظيم

سورة البقرة الآية: ٣٢

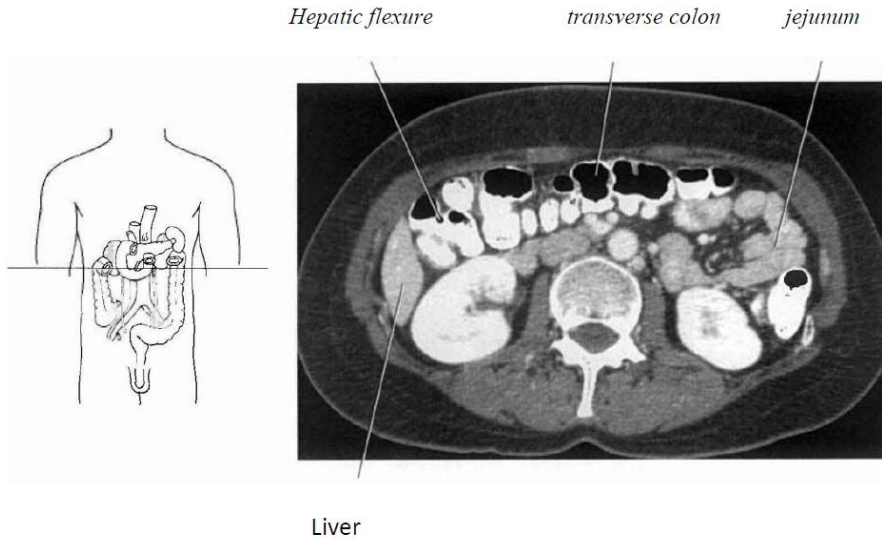

Fig. (1.3): Axial CT scan of hepatic flexure and transverse colon.

The transverse colon is located within the peritoneal cavity and is the largest and most mobile portion of the large intestine, making its position quite variable in the patient. The descending colon is retroperitoneal and continues inferiorly along the left lateral abdominal wall to the iliac fossa, where it curves to become the S-shaped sigmoid colon posterior to the bladder (**fig1.4**), and the sigmoid colon joins the rectum, which forms the terminal portion of the colon extending from the level of S3 to the tip of the coccyx (**Kelley and Petersen, 2013**).

US-PSTF	United States Preventive Services Task Force

List of Figures

Fig. No.	Title	Page No.
1.1a	Illustration of the anatomy of the large intestine	4
1.1b	Coronal CT colonography	5
1.2	Axial CT scan at the level ileo-cecal valve	6
1.3	Axial CT scan of hepatic flexure and transverse colon	7
1.4	Axial CT scan of the sigmoid colon	8
1.5	Illustration of the blood supply of the large bowel	10
1.6a	3D endoluminal view, Rectum with Foley's catheter and distal valve of Houston	11
1.6b	Coronal 2D image through the proximal valve of Houston	12
1.7a	3D endoluminal view of the sigmoid colon showing smooth folds in a patient with no muscular hypertrophy or diverticulosis	13
1.7b	Corresponding endoscopic view	13
1.8	3D endoluminal view, and corresponding endoscopic view of the descending colon, showing the colonic folds lying further apart.	14
1.9	3D endoluminal view looking "up" the splenic flexure into both the proximal and distal limbs	15
1.10	The 3D endoluminal view, showing the triangular shape of the lumen of the transverse colon and the corresponding endoscopic view	15
1.11	3D endoluminal view and corresponding endoscopic view of the cecum	16
1.12 a	Labial shaped ileo-cecal valve in both sagittal 2D view and 3D endoluminal view	17

List of Figures

Fig. No.	Title	Page No.
1.12 b	Papillary shaped ileo-cecal valve in both axial 2D and endoluminal 3D views	18
1.12 c	Ileo-cecal valve with opened orifice as showed in both 2D coronal view and 3D endoluminal view	18
2.1	illustration of the diverticular disease of the colon	20
2.2	Double contrast Barium enema	21
2.3	supine axial CT image at the level of the sigmoid colon, shows multiple diverticular orifices, as well as, a large extraluminal gas collection due to acute diverticulitis and abscess formation	22
2.4	optical colonoscopy shows multiple diverticular orifices ,with the corresponding 3D endoluminal view	24
2.5	Supine plain x-ray abdomen, showing thumb-printing of colonic mucosa	27
2.6	double contrast Barium enema, showing lead- pipe appearance of sigmoid and descending colon	28
2.7	axial CT showing the fat- halo sign.	30
2.8	Barium follow through showing duodenal narrowing in a case of Crhon's disease	35
2.9	illustration of the subtypes of adenomas	39
2.10	illustration of sites of carcinoma in different types of polyps	40
2.11	Paris classification of small flat adenomas	42
2.12	illustration of both Dukes' classification and TNM of colorectal carcinoma	44
3.1	Multiplanar sagittal reconstruction of a sessile polyp studied at 1mm(a), 2.5 mm(b) and 5 mm(c).	49

List of Figures

Fig. No.	Title	Page No.
4.1 a,b,c	[a]:2D CTC with patient in prone position, demonstrating a polyp submerged in a pool of contrast agent. [b] 2D CTC of the same patient with electronic cleansing of contrast agent showing the same polyp not submerged in contrast. [c] 2D CTC with the patient supine showing the same polyp surrounded by air due to movement of contrast agent	69
4.2	2D multiplanar view of a pedunculated polyp on a fold with coronal and sagittal reformat , and axial source data, 3D endoluminal view for correlation	79
4.3 a,b	Submerged polyp visible only through tagged fluid on 2D view (axial & sagittal reformat)	81 82
4.3c	3D endoluminal view supine and prone obscuring the visualization of the submerged polyp	82
4.4 a,b	Flat lesion seen at supine and prone (axial and sagittal reformat) & 3D endoluminal view	83 84
4.5	3D endoluminal panoramic view on antegrade flythrough, with "paint" function illustrating non visualized mucosal surfaces appears as darker color on the right and pink on the left	86
4.6	3D translucency tool permits evaluation of polyp density directly within the 3D viewing pane. Red represents soft tissue density.	88
4.7	Colon maps display an overview of colonic anatomy through surface rendering of the air mucosal interface at the colonic wall. Direct	89

	correlation with 3D endoluminal views aids in localization and orientation during 3D fly through cine navigation.	
4.8	6mm sessile polyp on a haustral fold, this polyp may be more difficult to distinguish from the haustral fold on a 2D axial image than on the corresponding 3D image.	90
4.9	Flattened view, the complete colon is displayed on the monitor, being divided into three strips	94
4.10	Point to point correlation between flattened view and 2D/3D images showing a 9mm pedunculated polyp on the 2D/3D images, that has an elongated appearance on the virtual dissection image "distortion of polyp morphology"	95
4.11	Annular constricting mass on flattened view.	96
4.12	Unfolded cube projection	97
4.13	Panoramic endoluminal display "Band" view	100
5.1 a,b	annular mass of the ascending colon in a 94-year old woman	107
5.1 c,d	Enhancement of the neoplastic mucosa is evident using abdominal window level setting after IV injection of iodinated contrast agent, with 3D endoluminal view.	108
5.2 a,b, c,d	Annular mass in the ascending colon with pericolonic fat stranding	109
5.3 a,b, c,d	Annular mass of the caecum misdiagnosed at barium enema examination	110
6.1	Classification of flat non polypoidal lesions	138

Introduction

CT Colonography, or what is known as virtual colonoscopy (VC), has been introduced to the medical society in the early 90's as a new modality for screening and diagnosis of colorectal carcinoma, ever since researches have blossomed to include clinical trials, software development, interpretation of visualization methods, radiation dose evaluation and the study of extracolonic findings (*Dachman and Yoshida, 2003*).

In the early 1980 CT technology showed a rapid advancement, from single slice scanners to helical imaging which permitted the acquisition of a contiguous volume of anatomy during a single breath hold. At the same time, computer technology was rapidly advancing to allow virtual reality simulations.

Intravenous contrast enhanced CT had already been well established as a means of staging an already known cases of cancer colon, and inflation of the colon with gas to improve the visualization of the colon was done as early as 1981. Researchers at New York University reported then that the distention of the colon with gas helped in raising the detection rate of cancer colon to 95% versus 68% if no special attempts were made to promote visualization of the colonic wall (*Laghi et al., 2013*).

The key invention for creating the 3D endoluminal fly-through method, was the work of Dr. David J. Vining, his inspiration for creating virtual colonoscopy as it is known nowadays was brought about by combining the advances in helical CT scanning technology with virtual reality computing that is used in flight simulator games, thus enabling him to navigate the volume of data generated by helical CT, and literally travel inside a simulation of the human body.

The first trial for the VC examination was done in September 1993, the single-slice spiral CT scanner that was used took approximately 1 minute to scan the patient during an attempt breath-hold, and the VC flight required more than 8 hours for the computer to process. Today, multidetector CT scans the body in a matter of seconds, and 3D processing occurs in real time on laptop computers.

Early clinical trials of VC yielded promising results, with some pioneer researchers reported high sensitivities exceeding 90% for the detection of polyps $\geq 1\text{cm}$, while others countered those results by other less appealing results. Those differences were attributed to several factors including; the type of patient cohort, training and experience of the readers and 2D versus 3D analysis technique (*Laghi et al., 2013*).

Near the end of the first decade of the new millennium, a study led by Dr. Perry Pickhardt, represented the largest screening trial to date with the evaluation of over 1,200 patients in the military. New technological breakthroughs were introduced, including stool tagging and subtraction, use of segmental unblinding to improve the reference standard beyond colonoscopy, and use of 3D as a primary image display review. Dr. Pickhardt's study set a benchmark of 90% sensitivity for the detection of polyps ≥ 1 cm and 80% for 6-8mm polyps in asymptomatic patients at low risk (*Laghi et al., 2013*).

As the first decade closed, studies evolved and new technologies emerged such that some recent studies show good sensitivity for the identification of non-polypoidal (flat) lesions as well. Furthermore, there are some researches to test the reliability of CTC as a screening program for early detection of cancer colon, yet it is not finally established.

Anatomy of the Colon

The colon is the last part of the intestinal canal, constituting the second main division of the large intestine with the other two parts being the caecum and the rectum (*Kelly and Peteresen, 2013*).

The large intestine (large bowel) lies inferior to the stomach and liver and almost completely frames the small intestine. It has a larger diameter and thinner walls than the small intestine and is approximately 1.5 meters long, starting at the ileo-cecal junction and ending at the anus. The outer, longitudinal muscle of the large intestine forms three thickened bands called *taenia coli* that gather the caecum and colon into a series of pouch like folds called *haustra* (*fig1.1a*). On the outer surface of the large intestine there are small fat-filled sacs of omentum called the *epiploic appendages*.
