Hand grip strength: A tool of nutritional assessment in prevalent hemodialysis patients

A thesis

For fulfillment of Master Degree in Internal Medicine

Submitted by

DOAA BAKRY ABDUL FATTAH SAEID

M.B.B.Ch, Faculty of Medicine, Ain shams university

Supervised by

Prof. Dr. Magdy Mohamed Saeed Elsharkawy

Professor of Internal Medicine and Nephrology
Faculty of Medicine – Ain Shams University

Dr. Ahmed Mohamed Tawfik

Lecturer of Internal Medicine and Nephrology
Faculty of Medicine – Ain Shams University

Dr. Reem Mohsen Elsharabasy

Lecturer of Internal Medicine and Nephrology

بِسْمِ اللَّهِ الرَّحْمَنِ الرَّحِيمِ

قالوا

لَسْبَدَّ اِنَّا لِمَعْلَمٍ لَنَا

اِلا مَا عَلِمْتُنَا اِنَّكَ اَنْتَ

الْعَلِيمُ الْعَظِيمُ

صدق الله العظيم

سورة البقرة الآية: ٣٢

Acknowledgement

My thanks first to **"Allah"** who give me the ability and strength to complete this work

I would like to express my indebtedness and deepest gratitude to **Prof. Dr. Magdy Mohamed Saeed Elsharkawy**, Professor of Internal Medicine and Nephrology, Faculty of Medicine, Ain Shams University for his valuable advice, guidance and constructive criticism, also for the invaluable assistance and efforts he devoted in the supervision of this study.

I'll never forget, how co-operative was **Dr. Ahmed Mohamed Tawfik**, Lecturer of Internal Medicine and Nephrology, Faculty of Medicine, Ain Shams University, also he was encouraging all the time. It is honorable to be supervised by him.

I would like also, to express my great thanks to **Dr. Reem Mohsen Elsharabasy**, Lecturer of Internal Medicine and Nephrology, and Faculty of Medicine – Ain Shams University. Her valuable advises and continuous support facilitated completing this work.

I'd like to give my warmest appreciation to my family and my friends who always give me a great support.

I would like to thank my colleagues and everyone who made this work possible and enjoyable.

Doaa Bakry

ABSTRACT

Background: Malnutrition is a common problem in patients with end stage renal disease (ESRD) undergoing hemodialysis that is associated with increased morbidity and mortality. There are several clinical, nutritional, and biochemical parameters that may be indicative of PEW in patients using hemodialysis (HD). Handgrip strength is a simple, quick, non-invasive, inexpensive, rapid, and objective procedure. In addition, it has other advantages as a diagnostic/screening tool for nutritional assessment. However, HGS relies on the motivation of the subjects, and therefore it is imperative that researchers and clinicians are sufficiently trained in HGS assessment. L-Carnitine supplementation, levocarnitine is an amino acid derivative which is an essential cofactor of fatty acid metabolism, may improve several situations.

Aim of the Work: The aim of our study, a longitudinal observational study, is to assess HGS as an independent tool for assessment of the nutritional status in hemodialysis patients. This study can also show the significance of the commitment to high protein diet (1.2- 1.4 g/ kg/ d) and receiving L-carnitine (10-20 mg/kg intravenously after each dialysis session) and its effect on the handgrip strength and other studied nutritional tools .

Patients and Methods: In our study, a longitudinal observational study, study duration was 3 months after washout period; our population is all End Stage Renal Disease patients in Kasr Al-Ainy Hemodialysis Unit, Cairo University. The unit provides hemodialysis and medical service for 104 patients from whom 50 were excluded and 54 patients were enrolled.

Results: the study showed comparison between both studied groups regarding the studied laboratory parameters and different nutrition assessment tools showed no statistically significant differences. The study showed Comparison between the effect of high protein diet and L Carnitine (pre and post) in patients of group B on the studied nutritional tools and laboratory parameters. Again HGS was the only tool that showed statistical significance. %BF(body fat) assessed by anthropometry was negatively correlated with HGS. Also they found lower HGS values in patients on HD with higher estimates of abdominal fat deposition. Thus, it seems that low muscle mass can occur despite fat accumulation, and one possible explication for this would be the proinflammatory phenotype presented by individuals with abdominal fat deposition. This confirms that subjects can have normal or higher BMI and have a depletion process, thus increasing the need for screening procedures related to functional status.

Conclusion: In this study, we concluded that HGS was the only significant (p value: <.001), while all other nutrition assessment tools didn't show any significant difference. The correlation between nPCR and HGS was statistically significant (p value:.001, r:.616). L-carnitine supplementation has no role over commitment to high protein diet only regarding improving the nutritional status and hemoglobin level in hemodialysis patients.

Keywords: Hemodialysis, Handgrip strength, L-carnitine, Nutritional assessment, High protein diet.

INTRODUCTION

Protein–energy wasting (PEW) is common in patients with chronic kidney disease and is associated with increased morbidity and mortality. There are several clinical, nutritional, and biochemical parameters that may be indicative of PEW in patients undergoing hemodialysis (HD) (**Mafrá et al., 2008**). Protein–energy malnutrition (PEM) is defined as a lack in supply of sufficient energy or protein to meet the body’s metabolic demands as a result of either an inadequate dietary intake of protein, intake of poor quality dietary protein, increased demands due to disease, or increased nutrient losses (**Kuhlmann et al., 2007**).

Malnutrition develops during the course of chronic kidney disease (CKD). CKD stages 3 and 5 are associated with a spontaneous reduction of the mean protein intake from 1.0 g/kg body weight/day to about 0.6–0.8 g/kg body weight/day accompanied by a reduction in energy intake. There are little data on the prevalence of PEM in pre-dialysis CKD stages, but a change in body composition including a reduction in body cell mass has been reported (**Bellizi et al., 2006**). The presence of protein energy malnutrition at the initiation of dialysis therapy is associated with higher risks of mortality and morbidity (**Segall et al., 2014**).

According to the International Society of Renal Nutrition and Metabolism (ISRNM) expert panel, PEW is diagnosed if there are low serum levels of albumin, transthyretin or cholesterol as well as decreased body mass (low or decreased body/fat mass or body mass loss with low intake of protein and energy), and decreased muscle mass (muscle wasting or sarcopenia) (**Fouque et al., 2008**). Decreased muscle mass appears to be the most valid criterion for the presence of PEW (**Axelsson et al., 2006**).

However, it is often difficult to diagnose decreased muscle mass or muscle loss accurately (**Mak et al., 2006**). In this setting, functional tests may be the most sensitive and relevant indicator of nutritional status alterations (**Norman et al., 2005**).

An ideal method for assessing the nutritional status of patients should include dietary intake, nutritional requirements, functional status and body composition. However, in the absence of a gold standard, scientists tried to identify new methods capable of accurately diagnosing malnutrition. Many tools have been used, however; their validity is still controversial (**Garcia et al., 2013**).

Handgrip strength (HGS), a measurement of the maximal voluntary force of the hand/arm, has been described as a useful tool in assessing muscle function because it is a noninvasive, rapid, objective, and inexpensive procedure (**Leal et al., 2011**).

Testing grip strength is a popular assessment used by occupational therapists in a range of clinical settings. It is fast, easy to perform, reliable and produces a result which is simple to record. Results of grip strength testing have been used to determine a baseline measure of performance against which change can be compared, as well as comparison of results to normative data (**Mills et al., 2002**).

Grip strength was the only assessment technique recommended for the measurement of muscle strength, and was the simplest method for assessment of muscle function in clinical practice. Longitudinal studies confirm that grip strength declines after midlife, with loss accelerating with increasing age and through old age (**Bohannon, 2001**).

Grip strength can be measured quantitatively using a hand dynamometer (**Stalenhoef et al., 2002**).
