Acknowledgment

*First thanks to **ALLAH** to whom I relate any success in achieving any work in my life.*

*I wish to express my deepest thanks, gratitude and appreciation to **Prof.Dr.Hanan Mohammed Saleh**, Professor of Dermatology, Venerology and Andrology Faculty of Medicine, Ain shams University for her meticulous supervision, kind guidance, valuable instructions and generous help.*

*Special thanks are due to **Prof .Dr. Mohamed Taha Elsayed**, Professor of Microbiology and Immunology Faculty of Veterinary Medicine, Zagazig University for his sincere efforts, fruitful encouragement.*

*I am deeply thankful to **Dr. Ghada Fathy Mohammed**, Assistant Professor of Dermatology, Venerology and Andrology Faculty of Medicine; Ain shams University for her great help, outstanding support, active participation and guidance.*

Mai Abdel-Naby Hamed

S. hyalinum	Scytalidium Hyalinum
SDA.....	Sabouraud dextrose agar
SDA+C	Sabouraud's dextrose agar medium with chloramphenicol
SDC+C+C	Sabouraud's dextrose agar with cyclohexamide and chloramphenicol
Spp	Species
SWO	Superficial white onychomycosis
T. equinum	Trichophyton equinum
T. erinacei.....	Trichophyton erinacei
T. mentagrophytes	Trichophyton mentagrophytes
T. rubrum	Trichophyton rubrum
T. verrucosum.....	Trichophyton verrucosum
TDO	Total Dystrophic Onychomycosis
TIRF.....	Total internal reflection fluorescence
UV light	Ultra violet light

ABSTRACT

Onychomycosis is a fungal infection of the toenails or fingernails that can cause serious complications...in the present study 30 patients of clinically suspected onychomycosis of finger and/or toe nails subjected to examination by fluorescence microscope using acridine orange stain and H&E stain, mycological culture, KOH 10% direct microscopic examination and H&E stained specimens' examinations under light microscopy were also done.

Key words: onychomycosis, fluorescence microscopy .H&E stain and Acridine orange stain.

INTRODUCTION

Onychomycosis is a fungal infection of the toenails or fingernails that may involve any component of the nail unit, including the matrix, bed, or plate. Onychomycosis can cause pain, discomfort, and disfigurement and may produce serious physical and occupational limitations, as well as reducing quality of life (*Tosti et al.*, 2003).

Accurate diagnosis is important since the treatment of onychomycosis can be long-standing, expensive and may be accompanied by severe adverse effects (*Allevato*, 2010) currently; the diagnosis is made by clinical suspicion along with KOH examination followed by culture of the samples (*Richert*, 2009). The sensitivity and specificity of the potassium hydroxide examination and culture depend on the center where the study is conducted and can be as low as 10%; when clinical suspicion of onychomycosis is high despite having a negative KOH examination and a negative culture, periodic acid-Schiff (PAS) staining of nail clippings can be used in the diagnosis of onychomycosis, but it is invasive and expensive compared to direct examination (*Jesús-Silva et al.*, 2010).

Special illumination techniques such as ultraviolet (UV) light (Wood's lamp) have long been used in clinical dermatology for diagnostic purposes in dermatopathology, UV light is frequently used to confirm the presence of immune

deposits in skin (*Caplan, 1977*). Utilization of ultraviolet light in the diagnosis of fungal infection ranges from *in vivo* diagnosis of dermatophytic infection to *in vitro* tissue diagnosis of fungal infection by immunofluorescent techniques (*Rao et al., 2004*).

fluorescence microscope is an optical microscope that uses fluorescence and phosphorescence instead of, or in addition to, reflection and absorption to study properties of organic or inorganic substances (*Spring and Davidson, 2004*).

Some prior studies have shown that pathogenic fungal species will fluoresce when examined under a fluorescent microscope, and this phenomenon has been advocated as a useful technique in the histopathologic diagnosis of fungal infections (*Mann, 1983; Margo and Bombardier, 1980*). Also fluorescence of pathogenic fungi has been previously shown when hematoxylin and eosin-stained sections are examined under a fluorescent microscope. There was a hypothesis about this phenomenon that it could aid in the evaluation of nail specimens for onychomycosis (*Elston, 2001*).

Most of these studies have focused on the study of systemic and deep fungal infections and most practicing dermatopathologists are unfamiliar with the use of fluorescent microscopy as a tool in the identification of fungal organism (*Elston, 2002*).

Fluorescent substances have attracted a lot of attentions in the past few decades due to their unique optical properties and applications in imaging of various inorganics (metal and anions), organics (drugs) and cells (*Kasibabu et al.*, ۲۰۱۵). The relative ease and availability of fluorescence microscopy in the dermatopathology laboratory warrants the investigation of this modality as a possible diagnostic tool in onychomycosis (*Idriss et al.*, ۲۰۱۴).
