Title of Thesis:

NUMERICAL INVESTIGATION OF VENTILATION METHODS IN AIR
CONDITIONED BATTERY STORAGE ROOM.

Key Words:

Ventilation; Hydrogen emissions; Indoor Air Quality; Batteries storage rooms; CFD

Summary:

Ventilation performance inside vented batteries storage rooms was investigated numerically using Ansys Fluent 16. The Model was built and meshed by Ansys design modeler part of Ansys software yielding around 2.6 million elements after making good use of symmetry boundary condition, and around 5.1 million in elements for the cases that have no geometrical symmetry. Validation was done at first against experimental published data and comparison between different turbulence models was performed. Standard k-ε turbulence model offered the nearest results to the experimental data.

Parametric Study is done to investigate the effect of three different factors on the efficiency of the ventilation system. First, the relation between the ACH employed and the average volumetric hydrogen. Second, the effect of changing inlets and outlets grilles location under fixed 8 ACH on hydrogen concentration inside the room. Third the effect of splitting the long single row into two halves vertical rows (double rack single step and double rack double step) on ventilation performance is investigated. Storage of the batteries in double vertical racks with double steps offered the best ventilation performance, using wall type inlet grille at the lower wall section and outlet grilles at the roof while the batteries rack are surrounded by curtains to act as local exhaust ventilation technique.

Acknowledgments

First, I would like to prostrate and praise to **THE ALMIGHTY ALLAH** whose blessing, guide, and mercy have been behind whatever successfulness may have been achieved in this work. I am eternally grateful that His blessings have come in the form of family and friends who have supported me in all my endeavors.

This Thesis would not been successfully completed without the generous support of many people. Firstly, I would like to express my deepest gratitude to my dearest supervisors, **Prof. Dr. Essam E. Khalil, Dr. Ahmed El Degwy and Dr. Esmail El Bialy** for their inspirations, patient guidance and valuable advice throughout the preparation of this Thesis. Without their kind support and tolerance, I can hardly complete this Thesis.

Secondly, I would like to give my sincere thanks to my colleges at work who helped me a lot, Engineer Hisham Ismail, Engineer Hesham Samy and Engineer Sherif El Nakeeb for their valuable technical guidance.

And Finally I would like to thank my dear parents for their encouragement and my dear wife Engineer Enas El Bedawy for her continuous support and care during the whole period. Also, I would like to thank my friends and colleagues for helping me in finding data and their valuable suggestions.

Abstract

Indoor air quality inside NiCd battery storage rooms is investigated in the current research. A proper ventilation system will ensure safe environment inside the battery room by keeping vented gasses within their safe threshold allowed by standards and yet achieve energy saving by avoiding unnecessarily high values of air change per hour (ACH). This should be done by selecting the optimum configuration of inlets and outlets grilles location as well as choosing the most suitable way of battery storage whether on single rack, double rack or double rack with double steps.

Indoor air quality inside the battery storage room subjected to hydrogen gas emissions from the stored vented batteries is investigated numerically throughout the current research using Computational Fluid Dynamics (CFD). ANSYS 16.0 software was used. Validation was done at first against experimental published data and comparison between different turbulence models was performed. Standard $k-\epsilon$ turbulence model offered the nearest results to the experimental data.

Parametric study is done to investigate the effect of three different factors on the efficiency of the ventilation system. First, the relation between the ACH employed and the average volumetric hydrogen concentration was found non-linear and inversely proportional. Second, the effect of changing inlets and outlets grilles location under fixed 8 ACH was found to have strong impact on hydrogen concentration inside the room. At fixed ACH proper design could offer low hydrogen concentration as low as 0.42 % vs. 6.11 % for the inefficient design. Third the effect of splitting the long single row into two halves vertical rows (double rack single step and double rack double step) on ventilation performance was investigated. Storage of the batteries in double vertical racks with double steps offered the best ventilation performance, using wall type inlet grille at the lower wall section and outlet grilles at the roof, while the batteries' racks are surrounded by curtains to act as local exhaust ventilation technique.

Chapter 1 : Introduction

1.1. General

Proper ventilation system in battery rooms is of crucial importance for safety considerations, not only for equipment safety, but for individuals as well. Stored batteries emit gases during charging, especially hydrogen gas which has explosive nature. If hydrogen concentration reached its explosive limit; explosion may occur. Accident took place at battery storage room in California, USA in 2001[1]. Fire department responded to a report of a building explosion, when firefighters entered the building they found several blown walls and visible smoke from a room that housed several large batteries. Firefighters also reported that a 40-foot section of the roof was missing just over the area of the explosion, collapsed numerous walls and ceilings throughout the building, and significantly damaged a large portion of the 50,000 sq. The facility was formerly a large computer center battery room. The company evacuated the building, moved out computer equipment; however the battery back-up system was left behind. Fire investigators along with hazardous materials response team from fire department determined that the cause of the explosion was that the batteries were charging for a long period of time with no ventilation, the detector was alarming and hydrogen continued to build up until it found an ignition source and hence the explosion occurred. The lesson to pass on is that ventilation is critical in these facilities. Great care should be taken to ensure that ventilation is adequate to dilute hydrogen gas emitted from the batteries. The below figures 1.1 and 1.2 show the damage caused by the explosion that took place.

Fig. 1.1: Damage caused by the explosion in battery room in California, USA [1].
