Acknowledgment

✍ Praises is to Allah and to Him alone. Every nerve ending, joint, limb, organ, and faculty of mine is indebted to **Allah (S.W.T.)** for all the blessings He granted me allowing me to Alhamdulillah (praise be to Him) successfully finish this essay. Words are insufficient to describe my gratitude and appreciation to Him in the whole process of the preparation, compiling and writing of this essay. In moments of distress, He guided me, showed me what to do, removed all obstacles from and lighted my path, inspired me, eased the task of writing, and gave me the energy so that I may put down words on paper. Without Him I would not have been able to undertake this task. What matters to me is that He accepts this contribution that He inspired me to write. Thank You Allah!

✍ I am indebted to my parents for their encouragement and support. They are a great inspiration to me, and their love for knowledge is the founding grounds for my love of knowledge. They invest so much in educating me and always encourages me to reach for the stars. I am truly indebted to both of them for their warmth and I hope that they would be proud of my achievements.

✍ My appreciation and gratefulness extends to my supervisors, **Prof. Dr. Refaat Refaat Kamel** Professor of General Surgery, Faculty of Medicine, Ain Shams University and **Prof. Dr. Hany Saeed Abdelbaset**, Assistant Professor of General Surgery, Faculty of Medicine, Ain Shams University and **Dr. Ahmed Nabil Kamal**, Lecturer of General Surgery, Faculty of Medicine, Ain Shams University, for their valuable time, guidance, insights, unconditional support, feedback, patience, encouragement, faith, opportunities to present my essay, and confidence in me over the time that made this formidable task attainable.

✍ **Mohamed Alaaeldin Maklad**

Abstract

Biliary complications after donor hepatectomy can result in significant morbidity. In this essay we try to research etiologies, risk factors, associations of donor biliary complications, also management and prevention of these complications according to multiple studies in multiple transplant centers worldwide. In conclusion, with careful donor selection and a standardized surgical technique, biliary complications can be minimized.

Keywords

Living donor liver transplantation. Donor biliary complications. Biliary leak. Biliary stricture. Endoscopic management.

Introduction

Transplant is the only known curative treatment option for end-stage liver insufficiency patients (*Jeon and Lee, 2011*).

Organs from live donors have provided a new form of hope for those who need liver transplants. Living-donor liver transplants offer the advantages of direct organ availability compared to deceased-donor transplants, the ability to conduct the procedure under the best conditions, and a reduced rate of primary organ dysfunction because of short-term cold ischemia (*Sugawara et al., 2002*).

However, living-donor liver transplants also give rise to some ethical concerns. Donor hepatectomy is the only surgical procedure that exposes the patient to a major and possibly fatal operation with no benefit to the donor, while providing the possibility of saving the recipient's life (*Cotler et al., 2007*).

Liver transplants were first conducted in pediatric patients with liver disease, using the parents of the patients as donors. The low rate of donor complications, high success rates in liver transplant recipients, and emotional satisfaction of the parents served to attenuate the ethical issues in pediatric liver transplants (*Roberts et al., 2004*).

This success achieved in pediatric liver transplants has paved the way for adult living-donor liver transplants which are characterized by the removal of 30% to 60% of the total volume of the donor's liver. Adult living-donor liver transplants had become widespread until the first donor death in 2002 (*Dirican et al., 2015*).

Despite geographic variations, today liver transplants are generally performed using live donors; thus, donor survival should be given the highest priority with consideration to ethical issues. Although the actual donor mortality rate is unknown, 19 donor deaths were reported in the largest series of patients to date and the average incidence of mortality was 0.2% (*Trotter et al., 2006*).

Hence, standardization of donor complications requires use of the modified Clavien-Dindo classification, and use of liver transplant databases, such as the European Liver Transplant Registry and the United Network for Organ Sharing, are required for storing the results (*Clavien et al., 1994*).

Although multiple donor hepatectomy procedures have been described, right and left lobe hepatectomy and left lateral segmentectomy are the most commonly applied. Liver insufficiency and sepsis are commonly deemed
