

BIOCHEMICAL AND GENTIC STUDY OF EGYPTIAN
PATIENTS WITH MUCOPOLYSACCHARIDOSIS

Thesis

Submitted For Partial Fulfillment of The M.D Degree
In Medical Human Genetics

By

Nermine M. Bahaa El- Din Ahmed
M.Sc. of Medical Human Genetics
Faculty of Medicine, Ain Shams U

Under the supervision of

Prof.Dr.Rabah Mohammed Shawky
Professor of Pediatrics & Genetics
Faculty of Medicine, Ain-Shams University

Prof.Dr.Eman Ahmed Zaky
Professor of Pediatrics
Faculty of Medicine, Ain-Shams University

Prof.Dr.Ekram Maher Fateen
Professor of Biochemical Genetics
National Research Center

Prof.Dr. Mahmoud Refaat
Professor of Genetics
Suez Canal University

Acknowledgement

First and foremost, I always feel indebted to “ALLAH” the most beneficent and merciful.

*Words cannot express the depth of my gratitude to my eminent professor, **Prof. Dr. Rabah Mohammed Shawky**, Professor of Pediatrics and Genetics, Faculty of Medicine, Ain Shams University, for her valuable suggestions, generous assistance, kind support, continuous and patient encouragement throughout this work. It is a great honour to work under her supervision.*

*My great appreciation and profound thanks to **Prof. Dr. Eman Ahmed Zaky**, Professor of Pediatrics, Faculty of Medicine, Ain Shams University, for her unlimited help, kind support, valuable supervision, remarkable guidance and fruitful advice.*

*I would like to express my deepest gratitude and profound thanks to **Prof. Dr. Ekram Maher Fateen**, Professor of Biochemical Genetics, National Research Center for her precious time, active participation, great help and honest assistance to complete this work.*

*I would like to express my deepest gratitude and profound thanks to **Prof. Dr. Mahmoud Refaat**, Professor of Genetics, Sues Canal University for his kind help and support.*

Also, I would like to express my appreciation to my colleagues in the Genetics Center, Ain Shams University for their help .Thanks to them, all.

Introduction

The mucopolysaccharidoses (MPS) are a group of heritable disorders each of which is produced by a deficiency of an enzyme required for the lysosomal degradation of sulfated glycosaminoglycans (*Neufeld and Meenzer, 2001*).

Mucopolysaccharides (or glycosaminoglycans) are large macromolecules composed of repeating frequently sulfated, disaccharide units attached to a protein core. A series of lysosomal acid hydrolases degrades the glycosaminoglycans by step-wise removal of the sulfates and carbohydrate residues (*Neufeld and Meenzer, 2001*).

There are 10 known enzyme deficiencies that give rise to six distinct MPS. Most of these enzymes have been extensively purified, their biosynthesis and processing have been elucidated and their primary structure determined from the sequence of the corresponding cDNAs (*Meenzer, 2003*).

Clinical symptoms eventually result from the lysosomal storage of the partially degraded glycosaminoglycans (*Scott et al., 1990*).

Incompletely degraded glycosaminoglycans accumulate in multiple organ systems leading to progressive worsening of the clinical manifestation. MPS share many clinical features, though in variable degrees. These include a chronic and progressive

course, multisystem involvement, organomegaly, dystosis multiplex and abnormal facts. There is clinical similarity between different enzyme deficiencies and conversely a wide spectrum of clinical severity within any one enzyme deficiency (*Muenzer, ٢٠٠٣*).

The MPS are inherited as autosomal recessive traits with the exception of the two subtypes of Hunter's disease, which are X-linked recessive (*Muenzer and Fisher ٢٠٠٣*).

Disorders that result in heparan sulfate storage have progressive central nervous system involvement. Affected patients may have macrocephaly and develop communicating hydrocephalus. Dermatan sulfate storage is associated with progressive visceral and bone involvement. Affected patients may have hepatosplenomegaly, cardiomyopathy or cardiac valvular involvement (*Muenzer, ٢٠٠٣*).

The cardiac and ocular manifestation are common in Egyptian patients with MPS. So regular cardiac examination, echocardiography and eye examination with slit lamp, fundus examination and regular measurement of the intraocular pressure in patients with MPS is necessary (*Shawky et al., ٢٠٠١*).

Hurler syndrome or mucopolysaccharidosis type ١ (MPS-١) was one of the first to be described (*Hurler, ١٩١٩*). It result from deficient activity of α -L-iduronidase (*Scott et al., ١٩٩٥*).

Simple enzyme assays are available for the diagnosis the MPS, prenatal diagnosis following amniocentesis or chorionic villus biopsy is possible for all MPS. (*Wenger et al*, 1983).

Scott et al., (1990) demonstrated that the IDUA gene spans approximately 19 Kb and it split into 14 exons. The first 5 exons are separated by an intron of 566 bp; a large intron of approximately 13 Kb follows and the last 10 exons are clustered within 4,0 Kb.

Bunge et al., (1994) found that the 5 common nonsense mutations, W45X and Q67X were identified in 33% and 30% of mutant alleles respectively. He identified 13 novel and 5 previously reported mutations of IDUA, covering 88% of mutant alleles and 86% of genotypes. In Caucasian population, the mutation trp 45-to-ter had previously been identified as a common MPSI mutation.

Supportive management with particular attention to respiratory and cardiovascular complications improve the quality of life for patients and their families. Early diagnosis of mucopolysaccharidosis is important because of the effectiveness of bone marrow transplantation and enzyme replacement therapy as efficient methods of treatment of MPSI before the appearance of manifestations (*Muenzer*, 2003).
