My Family

Acknowledgment

I wish to express my sincere gratitude and indebtedness to Prof. Dr. Amin Gad El Rab, Prof. of Ophthalmology, Ain Shams University, for his valuable help, constant support and continuous encouragement all through this work.

I am greatly indebted to Dr. Mervat Salafi, Assis. Prof. of Ophthalmology, Ain Shams University, for her precious guidance, valuable suggestions and continuous encouragement.

Finally I would like to thank every member in the Ophthalmology Department, Ain Shams University especially Prof. Dr. Amira Mounir, for her continuous great help.

Ahmed A. Sadek

LIST OF FIGURES

Fig. No.	Title	Page
1	Keratotomy wound contains an epithelial plug	29
2	Keratotomy wound after successful period of healing with slight epithelial plug	29
3	Human cornea 43 months after keratotomy showing no epithelial plug, healing of the stroma and the epithelium	30
4	Human cornea after successful keratotomy showing no epithelial plug and no increased cellularity	30
5	Photokeratoscope projects lighted placido disk-like target onto patient's cornea	37
6	Video-photokeratoscope	37
7	Graphic representation of computer-analyzed keratographs from normal cornea:	41
8	Normalized scale. and absolute scale	43
9	The arrangement of colors in color-coded topography	44
10	Eye sys corneal analysis system	47
11	Color coded topographic maps of the	50
12	The five patterns of normal corneal topography	51
13	Rounded clear zone marker	56
14	Fixation instrument double pronged forceps with 13-mm spread	56
15	Axis marker and the protractor	58
16	Astigmatic marker for trapezoidal pattern	58
17	T-marker	59
18	L-marker	59
19	Diamond knife showing the knife blade footplate and handle with a micrometer	62
20	Gauge block	62
21	Marking the center of the optical clear zone	74
22	Marking the oval clear zone	74
23	Intraoperative measurement of the corneal thickness	77

24	Fixation of the globe with Kremer fixation forceps	77
25	Transverse incisions perpendicular to the steep meridian	78
26	Combined transverse and radial or semiradial.	80
27	Intersecting incisions	82
28	Trapezoidal pattern	85
29	Grouped radial and oval clear zone.	87
30	Corneal topography contour map and keratoscope photographs. Showing (A) Postkeratoplasty astigmatism and (B) After arcuate relaxing incision.	100
31	Corneal topography contour map showing (A) Postkeratoplasty symmetric astigmatism and (B) Symmetric relaxing incisions	103
32	Microperforation of the cornea	117
33	Macroperforation with which needs 10/0 stiches	117
34	Decentered clear zone	120
35	Incisions across the visual axis	120
36	Incorrect axis of incisions	123
37	Curvilinear incisions	123
38	Central epithelial defects	125
39	Veiling glare	130
40	Bacterial keratitis	133
41	A central stellate iron line	135
42	Epithelial basement membrane changes	135
43	Hypertraphic scar	138
44	Vascularization of the incision scar	138
45	Epithelial inclusions	141
46	Epithelial ingrowth	141
47	Cataract following keratotomy	144
48	Traumatic rupture of keratotomy scar with iris incarceration	144
49	Severe form of traumatic rupture of the globe	146
50	Severe iridocyclitis following refractive keratotomy	148
51	Photoablation in Excimer Laser.	155
52	Plume from 193-nm excimer laser	156

53	Mask design for the correction of astigmatism using Holmium laser	164
54	The treatment pattern for correction of different astigmatic errors with Holmium laser	164

INTRODUCTION

INTRODUCTION

Visually significant astigmatism requiring treatment may occur in various clinical situations e.g. dystrophic and degenerative disorders of the cornea, postkeratoplasty patient, post-cataract surgery patient, and after trauma (*Agapitos, and Lindstrom, 1992*).

Naturally occurring astigmatism is quite common with up to 95% of eyes having some detectable astigmatic refractive errors. The incidence of clinically significant astigmatism reported varies between 7.5% and 75%. Between 3% and 15% of the general population may have an astigmatic refractive error of greater than 2.0D. (*Duke-Elder and Abrams, 1970*).

Post-operative astigmatism (post-cataract, post-keratoplasty, and post-refractive surgery) forms one of the major problems in visual rehabilitation for those patients. The incidence of post-operative astigmatism greater than 2.0D is approximately 25% to 30% (*Jampel, et al., 1986*) and (*Axt, 1987*).

The major symptoms of astigmatism is decreased uncorrected visual acuity and distortion from meridional magnification which is rarely present in the uncorrected

astigmatism, and more significant with spectacle correction. In refractive errors such as simple myopia and simple hyperopia, patients are able to see clearly to some degree at near and at distance, respectively. In contrast, patients with compound astigmatism may not see objects in clear focus at any distance (*Agapitos et al., 1989*).

Astigmatic keratotomies are referring to operations on the cornea which are intended to alter the refractive state of the eye (flatten the steep meridian and steepen the unincised meridian 90° away) (*Bores et al., 1993*).

ANATOMY OF THE CORNEA

ANATOMY OF THE CORNEA

Macroscopically:

The cornea forms the transparent anterior one-sixth of the eye ball. It is the main structure responsible for the refraction of light entering the eye. It is responsible for $\frac{2}{3}$ of total refraction of the eye in non-accommodative state (*Snell and Lemp, 1989*).

Seen from the front, the cornea is convex and somewhat elliptical in shape. The approximate measurements are about 12mm vertically but about 11mm horizontally. Posteriorly the cornea is concave and circular, measuring about 11.5mm in diameter. The radius of curvature of the anterior surface of the cornea is about 7.8mm; that of the posterior surface, is 6.5mm. However, it should be pointed out that it is frequently more curved in the vertical than in the horizontal planes (astigmatism with the rule) (*Warwick, 1976*).

Structure of the cornea :

Microscopically, the cornea consists of five layers from without inwards. The epithelium, the Bowman's membrane, the substantia propria, the Descemet's membrane, and the endothelium.

A. Corneal epithelium :

The corneal epithelium is a five-to-seven layer (30 to 50 μ m thick) stratified squamous epithelium non-keratinized that is organized in a more orderly fashion than similar epithelia elsewhere in the body, a prerequisite for the formation of a smooth transparent optical surface (*Waring, 1992*).

The epithelium contains three morphologic types of cells - a single layer of columnar basal cells, standing in a palisade like manner, in perfect alignment. They are responsible for mitotic activity . Each has a slightly oval nucleus whose long axis is that of the cell and placed near the head of the cell (*Kenyon, 1987*).

These basal cells accumulate iron in disorders that produce depression in the corneal surface. This iron forms the stellate iron line seen in the vast majority of cases after keratotomy. Also melanocytes are present within the epithelium which is responsible for striate melanosis seen in keratotomy incisions (*Steinberg, et al., 1984*).

The middle zone of cells in the corneal epithelium is the wing cells or umbrella cells, in which nuclei are oval or rounded
