

LYMPHOCYTOTOXIC ANTIBODIES IN SYSTEMIC LUPUS  
ERYTHEMATOSUS

THESIS

Submitted For Partial Fulfillment in  
Master Degree

Of  
INTERNAL MEDICINE

By

Dr. TAREK FOUAD SHEHATA  
M.B.B.CH.

SUPERVISORS

Prof. Dr. MEDHAT EL SHAFEI

Professor of Internal Medicine  
Faculty of Medicine  
Ain Shams University.

Prof. Dr. ABD ELRAHMAN MOUSSA

Professor of Internal Medicine  
Faculty of Medicine  
Ain Shams University.

Dr. MONA RAFIK

Assistant professor of  
Clinical Pathology  
Faculty of Medicine  
Ain Shams University.

Dr. MOHAMED ELBENNA

Lecturer of Internal Medicine  
Faculty of Medicine  
Ain Shams University

Dr. MALAK HASSAN BAHGAT

Lecturer of Internal Medicine  
Faculty of Medicine  
Ain Shams University.

AIN SHAMS UNIVERSITY

(1990)

***To My Parents***

### ACKNOWLEDGEMENT

I wish to express my sincere thanks and highest appreciation to Prof. Dr. M. MEDHAT EL-SHAFEI and Prof. Dr. Abd EL-RAHMAN MOUSSA, Professors of Internal Medicine, Ain Shams University, for their most valuable advice, kind supervision and continuous encouragement throughout the work.

Full gratitude and acknowledgment are due to Prof. Dr. MCNA RAFIK, Assistant Professor of clinical pathology, Ain Shams University for giving me unlimited time, generous help and valuable suggestions especially in the practical part of this work.

I am deeply thankful to Dr. MUHAMMED EL-BENNA and Dr. MALAK HASSAN. Lecturers of Internal Medicine, Ain Shams University for their great help and advice in this study.

### LISTS OF ABBREVIATIONS

ADCC	: Antibody dependent cellular cytotoxicity.
AIDS	: Acquired immune deficiency syndrome
ALA	: Antilymphocyte antibodies.
ANA	: Antinuclear antibodies.
ANTI-H	: Antihistone
ANTI-N-DNA	: Anti-native DNA.
ANTI-RNp	: Antiribonucleoprotein.
BCRs	: B-cell receptors.
C	: Complement.
Con-A	: Concanavalin-A
CHF	: Congestive heart failure.
CLA	: Complement dependent lymphocytotoxic antibodies.
CML	: Chronic myelogenous leukemia.
CNS	: Central nervous system.
CPK	: Creatinine Phosphokinase.
CSF	: Cerebrospinal fluid.
CVA	: Cerebrovascular accidents.
DEJ	: Dermal epidermal junction.
DIC	: Disseminated intravascular coagulation.
ds-DNA	: double stranded-DNA antibodies
EBV	: Epstein-Barr virus.
ESR	: Erythrocyte sedimentation rate
Ig	: Immunoglobulin.
IL	: Interleukin
JRA	: Juvenile rheumatoid arthritis.
LBT	: Lupus Band test

LCTA : Lymphocytotoxic antibodies.  
 LE : Lupus erythematosus.  
 MCTD : Mixed connective tissue disease  
 MHC : Major histocompatibility complex.  
 MI : Myocardial infarction.  
 MLR : Mixed leukocyte reaction.  
 MNC : Mononuclear cells.  
 MW : Molecular weight  
 NK : Natural Killer  
 PBS : Phosphate buffered saline  
 PHA : Phytohaemagglutinin.  
 PPD : Protein purified derivatives  
 PWM : Pook weed Mitogen  
 RA : Rheumatoid arthritis  
 RBCs : Red blood cells.  
 SLE : Systemic lupus erythematosus  
 SS-A : Streptolysin S-A.  
 SS-B : Streptolysin S-B.  
 T<sub>H</sub> : T-helper  
 T<sub>S</sub> : T-suppressor.  
 TCRs : T-cell receptors.  
 VDRL : Venereal disease research laboratory.

# ***Introduction and Aim of the Work***

## INTRODUCTION

Systemic lupus erythematosus (SLE) is a disease with a more immunologic cause. Among the various etiologic factors of SLE is the infective theory. One of the most important points which favoured this theory is the presence of lymphocytotoxic antibodies (LCTA) in sera from patients with SLE. These antibodies were often seen following viral infections e.g. measles, Mumps, and infectious mononucleosis, and are not only seen in these patients but also in their household contacts.

The aim of the present work is to evaluate the presence of these lymphocytotoxic antibodies in Egyptian lupus patients and their households contacts.

## ***Review of Literature***

LYMPHOCYTE

The lymphocyte is a spherical cell (7-12  $\mu$ m diameter) with scanty cytoplasm and a round, slightly indented and somewhat eccentrically located nucleus, containing coarse masses of chromatin (Kristic, 1984).

Lymphocytes carry out many functions but one of these is unmistakably and is unique to them. It is the lymphocyte's ability to re-shuffle its genes in such a way that they can then produce receptors for antigens and via these receptors initiates a specific immune response. The receptors also provide the basis for distinguishing two kinds of lymphocytes:

T-lymphocytes differentiating largely in the thymus and B-lymphocytes differentiating largely in the bone marrow (in mammals ) or in the bursa of fabricius (in birds). The receptors of the T-lymphocyte , the T-cell receptors (TCR) is characterized by its ability to recognize two molecules or molecular fragments at the same time: an antigen (non self) and a molecule encoded in the genes of the major histocompatibility complex (MHC; self in the physiologic situation) (Shwartz, 1985). The receptors of the B-lymphocyte, the immunoglobulin (Ig) molecule, on the other hand, recognize one molecule only - the foreign antigen (non self). The two kinds of receptors also differ in the form in which they are produced by their respective cells. The B-cell receptor (BCR) is secreted by the lymphocyte and the TCR is

not. This distinction is however not absolute, in certain stages of B-cell development, the BCR, like the TCR, is integrated in the membrane and only acquires a secretory piece in the latter phase (Kronenberg, et al., 1986).

The two kinds of receptors also differ in their structure, but this difference is in detail rather than in the overall design. (Kronenberg, et al., 1986). Both receptors consist of two kinds of chain (heavy and light in BCR,  $\alpha$  and  $\beta$  in TCR), each chain is assembled from very similar basic molecules (domains), the receptor genes are assembled from similar elements (The V.D.J. and C. Segments).

#### Lymphocyte Function and Structure

The main physiologic function of lymphocyte is to distinguish self from nonself and to mount specific attack on non self. The recognition occurs via three sets of molecules TCR, BCR and MHC molecules. The TCR of T-lymphocytes recognises protein in the context of MHC molecules, normally self MHC molecules, ( Roitt , et al., 1989). If the recognition occurs at a certain stage of development of the organism or a certain phase of T-cell differentiation, in which only self molecules are present, the recognising cell is inactivated or eliminated. If it occurs outside this stage or phase and involves non self proteins, the T-cell develops into an effector cell which can influence the development of other cell (T-lymphocyte, B-lymphocyte

and other cells) or can kill the target cell with which it reacts specifically ( Roitt, et al., 1989). The B-lymphocytes probably recognise self and non self antigens indiscriminately and also recognise a large spectrum of substances..They normally avoid response against self by being dependent on signals from activated T-cells for stimulation. Even when they bind to a substance via their antigen receptors, most of them do not develop into effector cells (antibody-secreting plasma cells) until they recieved the go-ahead from T-cells which have encountered the same substance(Mitchison, 1971).

In addition to this main function (initiation of specific immune response) lymphocytes also carry out a host of other functions, largely through soluble substances (lymphokines) which they secrete. Most of the lymphokines are produced only after activation of the lymphocytes which normally occurs when the lymphocyte encounters an antigens.

#### Lymphocyte Surface membrane: structure and function:

The lymphocyte surface (plasma) membrane as for cells in general consists of lipid bilayer, integral membrane proteins and peripheral proteins. The lipid bilayer provides a surface barrier separating the cell contents from the extracellular environment regulating the flow of ions and nutrients/ metabolites between these compartments. It is composed of equal amounts of cholesterol and

phospholipids, but the exact composition is variable and reflects the lipid composition of the environment (Levis, et al., 1976). In lymphocytes, the peripheral membrane proteins are apparently located exclusively on the plasma membrane's cytoplasmic face. The integral proteins exposed on the cell surface mediate in particular the recognition of specific antigen either alone (B-cells) or in association with class I & II MHC antigens (T-cells) (Selvaraj, et al., 1987).

#### I. The T-cell receptors (TCRs):

T-cells recognise different antigen entities than do B-cells (Kronenberg, et al., 1986).

The T-cell marker is the T-cell antigen receptor TCR, there are two defined types of TCR,  $TCR_2$  is a heterodimer of two disulphide linked polypeptide ( $\alpha$  and  $\beta$ ),  $TCR_1$  is structurally similar to  $TCR_2$  but consists of  $\gamma$  and  $\delta$  polypeptides. Both receptors are associated with a complex of polypeptides making up the CD3 complex. Thus a T-cell is defined either by  $TCR_1$  or  $TCR_2$  which is associated with CD3. Approximately 95% of blood T-cell express  $TCR_2$  and up to 5% have  $TCR_1$ . The  $TCR_2$  bearing cells can be subdivided further into T-helper ( $T_H$ ) subset which is CD4+ and T-cytotoxic/suppressor subset ( $T_c/s$ ) which is CD8+. CD4+ T-cells recognise antigens in association with MHC class II molecules. While CD8+ T-cells recognise antigens in association with MHC class I molecules (Roitt, et al., 1989).

Two potential functions of TCR1 bearing cells are surveillance of epithelia and differentiation of T-cell, TCR<sub>2</sub> (α,β receptors) in the thymus (owen, 1988).

The CD<sub>4</sub> + set can be further subdivided functionally into:

1. Cells which positively influence the immune response of T-cells and B-cells - the helper cell function, which are CDW 29+
2. Cells inducing suppressor/cytotoxic functions in CD8+ cells- the suppressor inducer function which are themselves CD45 R+.

CD8 + cells can also be subdivided by a number of criteria and a variety of monoclonal antibodies into specific functional subsets. For example cells which recognise antigen in association with MHC molecules and produce IL-2 (CD 28+) and cells which do not recognise antigen in association with MHC molecules or produce IL-2 (CD11 b+). CD3 +/TCR1 cells represent a minority of circulating T-cells which are also CD4, CD8. These cells house into surface epithelia such as epidermis and are termed intra-epithelial lymphocytes (IEL) In interstitial mucosal epithelium TCR1 + cells also express CD8. It is probable that these cells represent a primitive cytotoxic population operating at the sites of entry of pathogens (Roitt, et al., 1989).

## II. B-cells:

B-lymphocytes represent about 5-15% of the circulating lymphoid pool and are classically defined by the presence
