

ASSESS THE EFFECT OF THE NURSE'S KNOWLEDGE AND
SKILLS ON THE CARE GIVEN TO THE ORTHOPAEDIC
PATIENT WITH TRACTION AND INTERNAL FIXATION

Thesis
Submitted To High Institute of Nursing
Ain Shams University

In
Partial Fulfillment Of The Requirements

For
The Degree of Master of Science in Nursing
Medical-Surgical Nursing.

By
HAMMIA FOUAD ABUALLA
B.Sc. in Nursing

Ain Shams University

1996

Supervisors

PROF. Dr. LAYLA KAMEL
Professor of Medical-Surgical
Nursing.

Dr. MAGDA ABD EL AZIZ KAMEL
Professor of Medical-Surgical Nursing
High Institute of Nursing
University of Alexandria

ACKNOWLEDGEMENT

With sincere gratitude, the researcher would like to acknowledge Dr. Layla Kamel, Professor Medical- Surgical Nursing Department, Alexandria University, Dr. Nabil Khalifa, Professor of Orthopaedic at Faculty of Medicine, Ain Shams University and Dr. Magda Abd El Aziz, Lecturer of Medical Surgical Nursing. Ain Shams University, for their supervision, encouragement, valuable advice, suggestions, constructive criticism and their help during the various phases related to the achievement of this thesis.

I would also like to thank the Directors, Matrons, Nursing Staff Members of Ain Shams specialized Hospital and El Demerdash Hospital especially the nurses of Orthopaedic Department, for their assistance and cooperation during the study.

Last but not least, my special gratitude to my husband Dr. Usama Fathy, my children and my parents for their encouragement, assistance and sustained moral support.

LIST OF TABLES

<u>Tables</u>	<u>Page No.</u>
1. Distribution of nurses' characteristics in both hospitals	28
2. Distribution of nurses' knowledge score level in both hospitals about reasons for using traction and advantage of skeletal traction over skin traction	31
3. Distribution of nurses' knowledge score level in both hospitals about the equipment needed to apply both skin and skeletal traction	32
4. Distribution of nurses' knowledge and performance score level in both hospitals in relation to traction apparatus ...	33
5. Distribution of nurses' knowledge score in both hospitals about the nursing care needed for the prevention of some complications.....	34
6. Distribution of nurses' performance score level in both hospitals in relation to skin, skeletal traction and internal fixation	35

TablesPage No.

7. Distribution of nurses'performance score level in both hospitals in relation to health teaching and general care to bedridden patients.....	36
8. Distribution of nurses'knowledge total score in both hospitals	37
9. Distribution of nurses'performance total score in both hospitals.....	38
10. Relationships of nurses'performance in both hospitals with knowledge	39
11. Relationships of nurses'knowledge in both hospitals with age in years	40
12. Relationships of nurses'performance in both hospitals with age in years	41

INTRODUCTION AND AIM OF WORK

INTRODUCTION

Multiple Trauma is a frequent admitting diagnosis of patients into a critical care unit. With multisystem involvement, these patients require close monitoring of all body systems. Furthermore, the patients' management entails frequently handling and treatment of injured musculo-skeletal tissues. Treatment of this system very often being in the form of skin or skeletal traction. (Millar et.al., 1985).

Julien, (1985) reported that the nurse is an important and responsible part of the Orthopaedic Team. To do this she is required to possess special knowledge and skills related to the musculoskeletal system as well as to various other systems namely integument, nervous, circulatory to name only a few. Her observation basic skills are also required, for it is by the early detection of deviation that complications can be minimized. Last but not least, communication skills are heavily made use of since the fractured patient is in many other aspects a healthy individual who is suddenly immobilized and forced to live, interact with people he had no hand in choosing.

Row and Dyer (1977), stated that nurses must be cognisant of the use and objectives of traction. The nursing care for the patient in traction as reported by Jones et.al., (1982) is complex and requires much time and patience. In planning care for the patient in traction one must be mindful about the needs of the patient and family to understand what the traction is for, as well as what may and may not be done and the rationale for these limitations. As mentioned by Row and Dyer (1977) the successful outcome of the treatment does not rest only on the doctor who initiated the treatment - but depends largely on the diligent and intelligent observation and care exercised by the nurse at the bedside.

Moreover, traction can be a frightening experience to the patient. Thus the effectiveness of the traction may be limited if the explanations and instructions are not clearly given and carefully followed (Jones et.al., 1978). Nursing the patient in traction as pointed out by Decent, (1982) requires total patient care, because all his basic needs are affected.

AIM OF THE STUDY :-

- 1- To assess the nurse's knowledge about the care of the Orthopaedic patient with traction and internal fixation.
- 2- To assess the nurse's skill in providing care to the Orthopaedic patient with traction and internal fixation.

**REVIEW
OF
LITERATURE**

REVIEW OF LITRATURE

Management of patients with fractures :-

Management of patients with fractures is threefold. It entails reducing the fracture, maintaining immobilization and restoring function (Davies, 1983).

Reduction by definition means that the broken bones are replaced into their correct anatomical position. This could be achieved through the use of either the closed reduction or the open reduction method. These methods vary basically in the maneuvre of intervention. **closed** reduction is a method by which bone alignment is achieved through the application of appropriate manual force, whereas in open reduction bone alignment is achieved surgically and maintained by some form of internal fixation (Monk 1981, Brunner 1983, Lewis and Collier 1983, and Lewis 1984).

However, realignment of the bone must be maintained. This is achieved by immobilization of the effected limb. Its importance is paramount since it will ensure healing and maintenance of the reduced bones in position. Fractures reduced by the closed method are immobilised by some form of external splintage such as plaster of Paris, splints, traction. Some form of external splintage is

sometimes used following internal fixation, which include, plates, screws, bone grafts, and intramedullary nails (Simon and Koenigsknesht 1982).

Whilst immobilization of the fracture is necessary activity of those parts not immobilised is important. Thus the necessary rehabilitative step must be taken in order to ensure the minimal functional damage to the affected part. This can be achieved by the establishment of a general and specific planned exercise regimen to be implemented and carried out as a daily routine during the immobilization phase (Armstrong et.al. 1979, and Beyers and Dudas 1984).

TRACTION

Traction has been defined as the maintenance of a steady pull on a body part by means of a force in order to approximate two bone fragments in alignment (Browne 1981, Keane and Muhl 1982, Iversen and Clawson 1982, Peters and Dudas 1984 and Howe et.al. 1984).

Principles derived mainly from physics are applied in the use of therapeutic traction. The therapeutic traction is accomplished by exerting forces in two directions i.e. traction and countertraction. (Luckmann and Sorensen 1980 and Sorrentino 1987). The force of traction must be stronger than the force
