

RELATION OF ZINC TO SOME OBSTETRIC COMPLICATIONS

Thesis

Submitted for partial fulfillment of the
Master Degree in Obstetrics and Gynaecology

By

Abdel-Sameh Mohamed Soliman
M.B., B.Ch.

Supervisors

Prof. Dr. KHALIL ISMAIL EL-LAMIE
Professor of Gynaecology and Obstetrics
Ain Shams University

Dr. MAGED ABOU SEEDA
Lecturer of Gynaecology and Obstetrics
Ain Shams University

Dr. ABDEL-AZIZ MOHAMED KAMAL
Assist. Professor of Occupational Medicine
Dep. of Community, Environmental and
Occupational Medicine
Ain Shams University

1990

سبحانَكَ لَا عِلْمَ لَنَا إِلَّا مَا عَلَّمْتَنَا
إِنَّكَ أَنْتَ الْعَلِيمُ الْحَكِيمُ

صدق الله العظيم

ACKNOWLEDGMENT

I would like to express by sincere appreciation and my deep gratitude to Prof. Dr. Khalil Ismail El-Lamie, Professor of Obstetrics and Gynaecology, Faculty of Medicine, Ain Shams University, for his fatherly valuable guidance, unfailing encouragement and kind supervision which all facilitated the performance of this work.

Also, I want to express my profound gratitude to Dr. Maged Abou Seeda, Lecturer of Obstetrics and Gynaecology, Faculty of Medicine, Ain Shams University, for his expertise supervision, continuous encouragement and helpful advice during the work of this thesis.

May I also express my thanks and respect to Dr. Abdel-Aziz M. Kamal, Assistant Professor of Occupational Medicine, Department of Community, Environmental Medicine, Ain Shams University for his cooperation.

Finally, I would like to express my deep thanks, respect and gratitude to Prof. Dr. Ahmed Abdel Karim, Professor of Occupational and Environmental Health, National Research Center for his valuable cooperation and his great help to me in the laboratory procedures.

**INTRODUCTION AND
AIM OF THE WORK**

INTRODUCTION AND AIM OF THE WORK

The role of trace elements in health and disease is still poorly understood. During pregnancy, a phase of rapidly increasing nutritional requirements, one would expect changes in the trace element levels to occur. Thus far, a decrease in maternal zinc, iron and calcium levels during pregnancy have been documented (Jameson, 1976). On the other hand, the maternal copper level increases towards the end of pregnancy (Prema et al., 1980). To what extent these changes are physiological and to what extent pathological, is largely unknown. Reports suggesting that deficiencies of certain trace elements may be involved in complications of pregnancy have been published.

Jameson (1976) reported decreased serum zinc levels in a group of patients with abnormal labour, atonic bleeding and premature birth.

Cherry et al., (1961) found that women experiencing hypertension and/or toxemia during pregnancy had significantly lower plasma zinc levels.

During the intrapartum period, lower plasma zinc levels were associated with a prolonged latent phase, a protracted active phase, labour > 24 hours and cervical and vaginal

lacerations (Lazebnik, 1988).

AIM OF THE WORK:

The purpose of the present study is to test the hypothesis that certain complications during the course of pregnancy and delivery will be related to abnormal plasma zinc level, as one of the indices of zinc status.

REVIEW OF LITERATURE

TRACE ELEMENTS

Trace elements are those elements whose total concentration in a 70 kilograms human is less than 4 grams (Henkin, 1976).

Our bodies depend on at least nine trace elements such as: iron, zinc, copper, manganese, iodine, chromium, selenium, molybdenum and cobalt for optimal metabolic functions (Aggett, 1985).

Studies of trace elements have been particularly aided by the recent development of novel techniques such as flameless atomic absorption spectrophotometry, gas-liquid chromatography, X-ray fluorescence and mass spectroscopy, which have allowed reliable measurement of several trace elements in different tissues.

Deficiency of an essential trace element results in a characteristic deficiency syndrome in a manner analogous to a specific vitamin or hormone deficiency. The deficiency syndrome is associated with a specific structural, functional, biochemical and physiological abnormalities. These abnormalities in turn, are prevented or reversed after administration of the deficient element. Similarly, toxicity may result from excess of these

essential elements. They perform functions indispensable to maintenance of life, growth and reproduction.

William and Thomas (1985), reported that improvement in analytical methods have expanded our understanding to the role of trace elements in human nutrition and disease. A summary of the data concerning body content, plasma concentration, functional role and deficiency appears in the following table (Table 1).

Calcium, magnesium, iron and zinc are quantitatively the largest, present in gram quantities. Copper, chromium, manganese, iodine and fluoride, however are found only in milligram quantities.

Table 1: Trace elements in cotton seed (Hodges, 1988)

Element	Body content	Concentration			Description
		seed, dried	seed, green	average intake	
Calcium	1000-2000 µg	5-10.5 mg/100 g	3-10.5 mg/100 g	0.2-1.5 g/day	0.1-0.5 g
Magnesium	25-50 µg	5-10 mg/100 g	1.5-2.5 mg/100 g	400 mg/day	100 mg
Iron	5-10 µg	5-10 mg/100 g	50-120 mg/100 g	12-15 mg/day	0.5-1.5 mg
Zinc	2-5 µg	5-10 mg/100 g	120 mg/100 g	10-15 mg/day	1 mg
Copper	100-150 µg	5-10 mg/100 g	100 mg/100 g	1.5-5 mg/day	0.5-1.5 mg
Selenium	10-20 µg	-	4-8 mg/100 g	50-1000 mg/day	50-1000 µg
Manganese	12-20 µg	5-10 mg/100 g	1.4 mg/100 g	1-8 mg/day	-
Molybdenum	10-20 µg	15 mg/100 g	1.4 mg/100 g	100 mg/day	50 µg
Chromium	6-8 µg	15 mg/100 g	1-5 mg/100 g	500 mg/day	100 µg
Cobalt	1-2 µg	15 mg/100 g	2-3 mg/100 g	200 mg/day	30-60 µg

1. The highest concentration of iron is 12.7 g/100 g in seedlings, but it is higher than the average of plants before the

ZINC

The content of zinc is approximately 1.4 to 2.3 gm in a 70 kilogram man with a 20% of this amount in the skin. Circulating concentrations can be readily measured and average 121 ug/100 ml in serum and somewhat more than ten times this concentration in red blood cells (Prasad et al., 1970).

Evans et al., (1973) showed that, although intake of zinc is between 10 and 15 mg per day, absorption is usually low, representing less than 10%, and is decreased by certain binding agents, particularly phytates which are present in various cereals.

Zinc is a factor in a number of enzymes, including alkaline phosphatase (found in liver and bone), carbonic anhydrase, carboxy peptidase (from the pancreas), and lactate, malate and alcohol dehydrogenase. Zinc is also of importance in the B-cells of the pancreas and may be involved in the crystallization of insulin in the granules within the cells (Hambidge, 1978).

Zinc has an important role in the synthesis of DNA and protein, as shown by the reduced incorporation of radioactivity from thymidine into nuclear DNA in zinc

deficiency. This impairment can be overcome by injecting zinc in a short time before giving thymidine. The effects of zinc on the activity of ribonuclease offer one explanation for these effects on nucleic acid synthesis. Zinc is an inhibitor of this enzyme, and in deficiency states the activity of ribonuclease might be enhanced (Brandes et al., 1980).

Experimental zinc deficiency has been produced in several laboratory animals and has been documented with reasonable certainty in human beings. Zinc deficiency in human is characterized by dwarfism and hypogonadism (Prasad et al., 1970).

William and Thomas (1985), showed that many patients have come from certain villages in Egypt and Iran in which the ingestion of diets high in cereals might impair the absorption of zinc. The subjects in question are usually males and show a marked delay in onset of sexual development, pubic hairs are sparse or absent and the testes are small. Facial hair is sparse and hepatosplenomegaly is frequent. Administration of zinc accelerated growth of these boys and lead to an enhanced rate of sexual development. On this basis, it appears that zinc deficiency can be a causative factor in human disease. The mechanism by which zinc appears to impair growth is unclear. It is known to be
