

RADIOLOGY AND IMAGING
OF NORMAL ADULT KIDNEY

THESIS

SUBMITTED IN PARTIAL FULFILMENT OF
MASTER DEGREE IN RADIODIAGNOSIS

PRESENTED BY

HASSAN MOHAMMED HASSAN
M.B.B.CH.

SUPERVISORS

DR. LAILA GALAL
PROFESSOR OF RADIODIAGNOSIS
AIN SHAMS UNIVERSITY

DR. MEDHAT GHALIB
HEAD OF RADIODIAGNOSIS DEPARTMENT
MAADI ARMED FORCES HOSPITAL

FACULTY OF MEDICINE
AIN SHAMS UNIVERSITY

1986

20625

ACKNOWLEDGEMENT

I would like to express my deep thanks to all those who participated in giving their golden knowledge , to those who honoured me and gave glints on my way to knowledge .

I am grateful to Professor Dr. LAILA GALAL Professor of Radiodiagnosis , Ain Shams University for her unfailing advice, supervision , constructive criticism encouragement and guidance, as well as her kind attitude and moral support .

I am also grateful and I wish to express my deep gratitude and thanks to Professor Dr. MEDHAT GHALIB Head of Radiodiagnosis Department , Meadi Armed Forces Hospital for his generous help , kind advice and continuous supervision .

My appreciation is extended to my teaching staff , colleagues and technical staff for their kind help .

HASSAN MOHAMMED HASSAN

INTRODUCTION AND AIM OF WORK

INTRODUCTION AND AIM OF WORK

Urinary trouble is a common complaint among Egyptian , this being true if we take into consideration the prevalence of urinary Bilharziasis being a predisposing factor to most urinary problems .

Although the clinical picture points to the diagnosis in most cases, yet radiological and laboratory investigation form an essential part for the proper diagnosis of the offending lesion and hence the best line of treatment .

Radiological assessment of kidney function and the morphologic appearance of the kidney and pelvicalyceal system form an integral part of the investigation particularly if operative management is considered . To achieve this goal , different radiographic techniques are resorted to depending upon the case .

Twenty cases of normal adult kidneys will be selected during urinary tract examination to be continued for other methods of kidney radiological and imaging examinations .

The aim of this work is to evaluate morphology and function of normal adult kidney by different radiological and imaging modalities .

EMBRYOLOGY OF THE KIDNEY

EMBRYOLOGY OF THE KIDNEY

The kidney is composed of several units called uriniferous tubules .

The tubules arise from the mesoderm of the intermediate cell mass or nephrogenic cord which lies between the somites and the intra embryonic coelom . During their development, vertebrates have developed three kidneys .

A - PRONEPHROS :-

It is the earliest and simplest kidney to appear. It is the permanent or functioning kidney of some lower animals as the annelids and few fishes .

B - MESONEPHROS :-

The second kidney to appear and is more advanced in structure and function than the pronephros. It is the permanent or functioning of larval fishes and amphibian.

C - METANEPHROS :-

It is the last kidney to appear . It is advanced than the pronephros and mesonephros . It is the permanent kidney of reptiles , birds and mammals .

The embryos of these animals develop at first a simple pronephros and then mesonephros and finally form the functioning metanephros .

THE METANEPHROS

It has a double origin being derived from : -

- 1 - Ureteric bud and its ramification .
- 2 - Metanephric cap : from the lower part of the nephrogenic cord .

Ureteric bud : -

It arises as a diverticulum from the dorsal and medial side of the lower part of the mesonephric duct close to the cloaca . This diverticulum extends at first dorsally and then cranially .

The ureteric bud elongates and its upper end is expanded to form the further pelvis of ureter from which arise the cranial , central and caudal tubules. From the later , arise secondary tubules and these in turn give rise to further tubules and the process is repeated . In the fifth month about twelve generations are formed while at Birth there are about twenty generations . The cranial and caudal tubules form the major calyces . The secondary tubules form the minor calyces. The tubules of the fifth order give rise to the papillary ducts . The other branches form the straight collecting tubules of the medulla .

The metanephric tissue surrounding the collecting tubules becomes divided into numerous spherical masses. These masses surrounded the ends of the tubules. As new collecting tubules arise progressively, each metanephric mass becomes subdivided into several smaller masses which will form the secretory tubules.

Each mass forms one of the secretory tubules. The spherical mass becomes converted into a hollow vesicle which becomes elongated and S shaped in appearance. One end joins the collecting tubules and the other blind end of the tubule forms the Bowman's capsule.

Further growth of the tubule leads to the formation of distal and proximal convoluted tubules. The remaining portion of the tubules forming the loop of Henle.

The first group of secretory tubules to appear are temporary and they degenerate. Any increase in kidney size after birth results from enlargement of the tubules already present. The human kidney is capable of secretion in the third month of foetal life. Since the placenta acts as an excretory organ, the renal function is either minimal or nil.

(CHARLES.W.RODEMER 1970)

Shape of the kidney :

In early stages the kidney is a lobulated organ , later these grooves disappear and the surface of the kidney becomes smooth . Lobulation is permanent feature in some animals and birds .

Migration of the kidney :

In early stages the kidney lies in the pelvic region . Later it migrates upwards till it lies in front of the upper part of the posterior abdominal wall .

Changes of blood supply of the kidney :-

During its migration , the kidney changes its blood supply . At first it receives its blood supply from the median sacral , the common iliac and then from the lower part of the abdominal aorta . Accessory renal arteries may occur , they may enter at the hilum or at the upper or lower poles of the kidney .

Rotation of the kidney :-

At first the convex border of the kidney is directed posteriorly while the hilum lies ventrally . Later the kidney rotates about 90 degree and the dorsal convex border becomes lateral .

(Harry wang 1972)

ANATOMY OF THE KIDNEY

ANATOMY OF THE KIDNEY

The kidneys are paired, retroperitoneal, bean shaped organs lying on each side of the vertebral column . Usually, the Rt. kidney is slightly lower than the left one due to the presence of the liver.

The upper pole is approximately 4 cm closer to the mid line than the lower pole, so the kidneys lie in an oblique position.

The kidneys lie on the upper part of the posterior abdominal wall opposite the bodies of the T₁₂ and L₁, 2, 3, vertebrae . (DAVIS 1967)

Each kidney has a vertical slit in its medial border which is called the hilum . Through the hilum the renal artery enters the kidney and the renal vein and the ureter leave it .

The transpyloric plane passes through the hilum of each kidney .

There are differences between the position of the two kidneys which are : -

1 . The Rt. kidney is $\frac{1}{2}$ inch lower in position than the left one .

2 . The upper end of the left kidney extends upwards as high as the vertebral end of the 11th ribs.

- 3 . The upper end of the Rt. Kidney does not reach higher than the upper border of the 11th rib or maximally 11th intercostal space .
- 4 . The lower end of the Rt. kidney extends downwards as to lie 1 ½ inches above the iliac crest (lower end of the 3rd lumbar vertebrae)
- 5 . The lower end of Lt. kidney lies 2 inches above the iliac crest . (BREWER AND FORD 1915)

From Behind , the kidney lies within a rectangular area which is drawn by 2 horizontal and two vertical lines :-

- 1 . The upper horizontal line is opposite the spine of T₁₁
- 2 . The lower horizontal line is opposite the spine of L₃ .
- 3 . The 2 vertical lines are drawn one inch and three inches from the median plane . (JOHN GARREY 1962)

The hilum of the Rt. kidney is opposite 9th lumbar vertebrae and the Lt. kidney is 2-3 cm higher . In maximum movement , it is about 5 cm or 1 ½ vertebral body occurs in change from recumbent to erect

position and during respiration .

The Lt. kidney is longer and narrower than the
Rt. one . (DR. SMITH 1981)

Measurement of the Kidney :

Length	12 cm	
Width	6 cm	
Thickness	3 cm	(GRAY 3 1958)

Each kidney has :

- 1 . Two borders (lateral and medial)
- 2 . Two surfaces (anterior and posterior)
- 3 . Two ends or poles (upper and lower)

The lateral border is convex while the medial
border is concave and contain the hilum .

The lateral border is regular and smooth.

The hilum contains the renal artery , renal vein and
the pelvis of the ureter which are arranged in the
following order : -

- 1 . The renal vein lies in the front.
- 2 . The renal artery lies in the middle
- 3 . The pelvis of the ureter lies behind .

(ELKIN 1980)
