

**PURIFICATION AND CHARACTERIZATION
OF HYALURONIDASE FROM CERASTES
CERASTES VENOM**

THESIS

Submitted in Partial Fulfilment for
the Master Degree in Biochemistry

By

1985

*DEDICATED
TO MY
FATHER & MOTHER*

This research project is carried out under grant No. 840505 by the Foreign Relation Coordination unit of the Supreme Council of Universities.

ACKNOWLEDGMENT

I would like to express my deepest gratitude to my advisor Dr. Mohamed Farid El-Asmar, Professor of Biochemistry, Faculty of medicine, Ain Shams University, for his technical assistance, guidance and generous help.

I want to express my gratitude and thanks to Dr. Fathy Tash, Prof. of Biochemistry, for his supervision, guidance, and true cooperation, and to Dr. Emtiaz Shaaban, and Dr. Rashwan Farag for their supervision and actual readiness to help.

My sincere gratitude and thanks are also extended to my professor, Dr. Salah El-Din Zaky Eid, Head of Biochemistry department, Faculty of medicine, Ain Shams University, for his encouragement and support.

Finally thanks to all my colleagues in Biochemistry department for being cooperative and helpful.

CONTENTS

AIM OF THE WORK

Aim of the work

Snake venoms are complex and concentrated mixtures of many enzymes and substances of marked biological concern

The understanding of the net effect of envenomation on the body of bitten victim requires a complete idea about the effect and role of each component separately. And hence the need for fractionation, purification and characterization of the different venom constituents.

The hyaluronidase enzyme was well known to occur in the majority of snake venom families. It has been implicated in the diffusion of the injected venom into and through tissues, but it has never been shown to definitely participate in this action.

Our task in such a study is to purify the hyaluronidase enzyme from one of Egyptian vipers venom, which is the Cerastes cerastes snake venom.

Characterization of both physical and kinetic behaviour of the enzyme will be explored.

Effect of temperature, pH, metal and non metal ions on its activity will be attempted.

Calculation of its Michaelis constant (K_m). for its preferable substrate, hyaluronic acid, is of great value for its characterization.

INTRODUCTION

GENERAL INTRODUCTION

In ancient civilization, the snake embodied the spirit of the earth. At this time, the snake was the attribute of all cosmogonies.

Snakes represented the spirit of air and earth and was the symbol of health, Knowledge, life, and fecundity. Aaron, the brother of Moses, turned rods into snakes, and placed a bronze snake on a staff, anyone who was the victim of snake poisoning was saved when he saw this symbol.

Jung (1964) told the curious story of the chemist Kekule who, in the 19th century, came to define the molecular structure of benzene, influenced by the memory of ancient symbols, he was dreaming one night of a snake holding it's tail in it's mouth and on awakening from his dream, related the circular shape of the snake to the cyclic structure of benzene.

The "ouroboros" of Africa is a snake which bites its own tail off since it fertilizes itself it is considered a "Source of life" Being venomous, it is also a "Source of death" so the "Ouroboros" is an expression of the idea of life and death at the same time (CHEVALIER, 1973).

In the 16th century, Van Helmont proposed his phlogistic theory, that snake venoms are "irritated spirits" which were "so cold" that they coagulated the blood in the veins and arrested the circulation.
