Cairo University  
2015

## *Acknowledgement*

*All praise, thanks and gratitude are due to ALLAH, the Cherisher and Sustainer of the worlds, for always bestowing countless bounties upon us.*

*I'd like to express my warm appreciation and cardinal thanks to Dr. Basma H. Gomaa; Professor of Medical Microbiology and Immunology, Cairo University, for her enthusiastic encouragement, persistent effort and support.*

*I owe special thanks to Dr. Lamiaa A. Madkour, Lecturer of Medical Microbiology and Immunology, Cairo University for her generous effort, honest advice, critical insight, meticulous supervision and patience.*

*I'd like to express my sincere gratitude and appreciation to Dr. Youssef M. Amin, Lecturer of Chest diseases, Cairo University, for his highly-valued help and cooperation.*

*Words truly stand short when they come to express my deep thankfulness to my family, to whom I owe a debt of gratitude.*

## **Abstract**

### **Background:**

Ventilator-associated pneumonia (VAP) is a type of nosocomial pneumonia associated with increased morbidity and mortality. Knowledge about the incidence and risk factors is necessary to implement proper preventive measures.

### **Objectives:**

To estimate the incidence and risk factors of VAP, as well as the most common etiological agents.

### **Methodology:**

A prospective cohort study was conducted from March 2014 to February 2015 at Kasr El-Aini University Hospital, Chest Intensive Care Unit. Hundred patients who were on mechanical ventilation (MV) for more than 48 hours were monitored for the development of VAP.

### **Results:**

Out of the 100 patients, 34 patients developed VAP. Univariate analysis showed that the duration of MV and trauma were significant risk factors for VAP. Multivariate analysis revealed that the duration of MV, trauma, diabetes mellitus, smoking and some comorbidities were also independent risk factors for VAP. The most common isolated pathogens were *Klebsiella* spp., *Pseudomonas* spp. and *Acinetobacter* spp.

### **Key Words**

VAP; risk factors; nosocomial pneumonia; nosocomial pathogens

## Introduction and Aim of the Study

Ventilator associated pneumonia (VAP) is considered the most common nosocomial infection among the critically ill patients admitted in the intensive care units (ICUs) (**Juneja *et al.*, 2011**). It is defined as pneumonia occurring more than 48 h after patients have been intubated and mechanically ventilated (**Koenig & Truwit, 2006**).

VAP is associated with significant morbidity and mortality; including prolongation of mechanical ventilation (MV) (**Rello *et al.*, 2002**) and ICU stay (**Fagon *et al.*, 1993** and **Heyland *et al.*, 1999**), increased risk of death (**Fagon *et al.*, 1993**), as well as increased hospital costs (**Safdar *et al.*, 2005b**).

Several risk factors have been reported to be associated with VAP, including the duration of MV, the presence of chronic pulmonary disease, sepsis, acute respiratory distress syndrome (ARDS), neurological disease, trauma, prior use of antibiotics and blood transfusions (**Tejerina *et al.*, 2006**).

Study of these factors offer prognostic information about the probability of developing VAP in individual patients and populations, help us to understand the mechanisms that may predispose to VAP and may allow risk stratification to target high risk patients for prevention strategies (**Cook & Kollef, 1998**).

The incidence of VAP ranges from 8-68%. Mortalities can range from 24-50% and even up to 76% when the infection occurs with certain microorganisms (**Chastre &Fagon, 2002**). The etiological agents vary from common organisms to multidrug resistant (MDR) pathogens that are difficult to treat (**Charles *et al.*, 2013a**). The diagnosis of VAP requires a high clinical suspicion combined with bedside examination, radiographic examination and microbiologic analysis of respiratory secretions (**Koenig & Truwit, 2006**). Detection of the causative organisms and their antibiotic susceptibility is crucial for diagnosis of VAP in order to initiate the appropriate antibiotic treatment; thereby reducing the adverse effects of inadequate antibiotic treatment on the patient prognosis (**Dey & Bairy, 2007**).

***Aim of this study:***

- 1- Estimation of the incidence of VAP among mechanically-ventilated patients in Kasr Al-Aini hospitals.
- 2- Assessment of the relation between different risk factors and the incidence of VAP.
- 3- Detection of the most common etiological agents of VAP.

## Epidemiology of VAP

Nosocomial pneumonia is an infectious process which develops within 48 hours after admission to the hospital and that was not incubating at the time of hospitalization. Ventilator-associated pneumonia (VAP) is considered as a subgroup of nosocomial pneumonia that develops 48 hours after the presence of an artificial airway and mechanical ventilation (MV) (**Ferrer *et al.*, 2008**).

From another point of view, VAP is defined as a pneumonia where the patient is on MV for >2 calendar days on the date of event, with day of ventilator placement being day 1, and the ventilator was in place on the date of event or the day before. If the patient is admitted or transferred into a facility on a ventilator, the day of admission is considered day 1 (**CDC, 2014**).

### • **Incidence of VAP:**

VAP is the most frequent ICU-acquired infection (**Morehead & Pinto, 2000 and Joseph *et al.*, 2009**). However; the incidence of VAP varies in different regions of the world, depending on the criteria used for diagnosis, the type of ICU, hospital resources and study population (**Joseph *et al.*, 2009**).

To facilitate and foster benchmarking between units and hospitals, the National Healthcare Safety Network at Centers for Disease Control and Prevention (NHSN/CDC) recommends expressing VAP as the number of infectious episodes per 1,000 ventilator-days. In its report

covering the period from January 1995 to June 2001, VAP ranged from 4.9 episodes per 1,000 ventilator-days in pediatric, 7.3 episodes per 1,000 ventilator-days in medical and 8.4 episodes per 1,000 ventilator-days in coronary to 13.2 episodes per 1,000 ventilator-days in surgical ICUs (NHSN, 2002). On the other hand, the WHO (2011) revealed that the incidence of VAP ranged from 5 to 24 episodes per 1,000 ventilator days. Meanwhile; data from developing countries reveal an incidence which ranges from 15.8-30.6 per 1000 ventilator-days (Joseph *et al.*, 2009). The rate of VAP in developing countries is higher than NHSN benchmark rates, and is associated with a significant impact on patient outcome (Arabi *et al.*, 2008).

In the United States, VAP was proposed as a quality-of-care indicator for ICUs (Melsen *et al.*, 2009). Between January 2006 and December 2007 in the United States, NHSN/CDC reported that VAP accounted for approximately 17% of the Healthcare Associated Infections (HAIs) in the ICU (Edwards *et al.*, 2009). Another study concluded that the incidence of VAP worldwide was 10-28% (Safdar *et al.*, 2004). However; the incidence of VAP in Egypt ICUs was about 2.5 times more. The highest incidence, 75% was noted in Ain Shams University and the lowest incidence, 16% was in Alexandria University, while the incidence in Mansoura University was 22.6% (Fathy *et al.*, 2013).

• **Classification and etiological agents of VAP:**

VAP can be divided into early-onset and late-onset disease. Early-onset VAP occurs during the first 4 days in which the patient receives MV (Craven, 2000). It is usually less severe, has a better prognosis and is more likely to be caused by antibiotic-sensitive bacteria. On the other

hand, late-onset VAP is often caused by MDR pathogens and is associated with increased morbidity and mortality (**Niederman & Craven, 2005**).

The common and unusual microbial causes of VAP documented by several investigators are listed in table 1 (**Niederman & Craven, 2005; Park, 2005 and Joseph *et al.*, 2010b**). These agents may be part of the host's endogenous flora, or may be acquired from other patients, health care workers, devices or the hospital environment (**Craven, 2000**).
