Acknowledgement

First and foremost, thanks to **Allah the Almighty** to whom I relate any success in achieving any work in my life.

I would like to express my very great appreciation to Professor **Prof. Dr. Emad El Din Abdel Wahab Korraa**, Professor of chest Diseases and Tuberculosis, for his precious instructions, expert supervision and valuable comments during the course of this work.

I would like to offer my special thanks and deep appreciation to **Dr. Rehab Maher**, Lecturer of chest Diseases and Tuberculosis for her help and valuable advice throughout the performance of this work.

Last but not least, sincere gratitude to *My Family* for their continuous encouragement and spiritual support.

INTRODUCTION

Asthma and chronic obstructive pulmonary disease (COPD) are a major public health problem because of their high and still rising prevalence, their associated morbidity, mortality and socioeconomic costs (**Bahadori et al., 2009; GOLD, 2011**).

Asthma is recognised as an allergic disease that develops in childhood, characterised physiologically by reversible airflow obstruction, and has an episodic course with a generally favourable prognosis, responding well to anti-inflammatory treatment. In contrast, COPD is typically caused by tobacco smoking, develops in mid to later life and is characterised by incompletely reversible airflow limitation that results in a progressive decline in lung function leading to premature death (**Gibson and Simpson, 2009**).

Although asthma and COPD are different diseases, differential diagnosis is sometimes difficult and may be impossible in some older patients (**Guerra, 2004**).

Furthermore, asthma and COPD may coexist: more than 40% of patients with COPD report a history of asthma, and asthma has been recognized to be a risk factor for developing COPD. Patients who have both COPD and asthma (overlap syndrome) have a more rapid disease progression, a worse

Introduction

health-related quality of life, more frequent respiratory exacerbations, increased co-morbidities and health care utilization than those with either disease alone (**Roberto de Marco et al., 2013**).

Overlap syndrome is recognized by the coexistence of increased variability of airflow in a patient with incompletely reversible airway obstruction. Patients typically have inflammatory features that resemble COPD, with increased airway neutrophilia, as well as features of airway wall remodeling. Overlap syndrome can develop when there is accelerated decline in lung function, or incomplete lung growth, or both. The risk factors for these events are shared, such that increasing age, bronchial hyper-responsiveness, tobacco smoke exposure, asthma and lower respiratory infections/exacerbations are significant risk factors for both incomplete lung growth and accelerated loss of lung function. Studying these events may offer new insights into the mechanisms and treatment of obstructive airway diseases (**Gibson and Simpson, 2008**).

AIM OF THE WORK

To evaluate the prevalence of asthma- chronic obstructive pulmonary disease (overlap syndrome) in Embaba Chest Hospital.

Chapter (1):

CHRONIC OBSTRUCTIVE PULMONARY DISEASE

Definitions:

COPD is a preventable and treatable disease state characterized by airflow limitation which is progressive, not fully reversible, associated with airway inflammation, hyperresponsiveness and systemic manifestations including skeletal muscle dysfunction, cachexia, cardiovascular and osteo-skeletal alteration. The airflow obstruction is generally due to chronic bronchitis or emphysema (**ATS, 2007**).

Chronic obstructive pulmonary disease (COPD) is a preventable and treatable disease with some significant extra pulmonary effects that may contribute to the severity in individual patients. Its pulmonary component is characterized by airflow limitation that is not fully reversible. The airflow limitation is usually progressive and associated with an abnormal inflammatory response of the lung to noxious particles or gases (**GOLD, 2010**).

This definition does not use the terms chronic bronchitis and emphysema and excludes asthma (reversible airflow limitation).
