

# **MANAGEMENT OF HIP DISLOCATION IN SPASTIC CEREBRAL PALSY PATIENTS**

*Essay*

*Submitted For Partial Fulfillment of Master Degree  
In “Orthopedic Surgery “*

*By*

**Mohammed Ibrahim Ibrahim El Ashmawy**  
*(M.B., B.Ch)*

*Under Supervision of:*

**Prof. Dr. Mohammed Reda Abdel Wahab**

*Professor of Orthopedic Surgery  
Faculty of Medicine – Ain Shams University*

**Dr. Mahmoud Ali Salah Eldeen Mahran**

*Assistant Professor of Orthopedic Surgery  
Faculty of Medicine – Ain Shams University*

**Faculty of Medicine  
Ain Shams University  
2016**

بِسْمِ اللَّهِ الرَّحْمَنِ الرَّحِيمِ

قَالُوا سُبْحَانَكَ

لَا عِلْمَ لَنَا

إِلَّا مَا عَلَّمْتَنَا

إِنَّكَ أَنْتَ

الْعَلِيمُ الْحَكِيمُ

صِرَاقُ اللَّهِ الْعَظِيمِ

سُورَةُ الْبَقَرَةِ (آيَةُ ٣٢)

*First thanks to **ALLAH** to whom I relate any success in achieving any work in my life.*

*I would like to express my sincere appreciation and my deep gratitude to **Prof. Dr. Mohammed Reda Abdel Wahab**, Professor of Orthopedic Surgery, Faculty of Medicine – Ain Shams University, for his faithful supervision, guidance and for his great support throughout the whole work,*

*I would like to express my great thanks to **Dr. Mahmoud Ali Salah Eldeen Mahran**, Assistant Professor of Orthopedic Surgery, Faculty of Medicine – Ain Shams University, for the tremendous effort he has done in this work. At last, I am indebted for my family.*

***Mohammed El Ashmauy***

# علاج خلع الورك في مرضى الشلل الدماغي التشنجي

رسالة

توطئة للحصول على درجة الماجستير في جراحة العظام

مقدمة من

الطبيب / محمد ابراهيم ابراهيم العشماوي

بكالوريوس الطب والجراحة

تحت إشراف

الأستاذ الدكتور / محمد رضا عبد الوهاب

أستاذ جراحة العظام

كلية الطب - جامعة عين شمس

الدكتور / محمود علي صلاح الدين مهران

أستاذ مساعد جراحة العظام

## **INTRODUCTION**

Cerebral palsy is a non progressive central nervous system affection usually associated with difficult births which was first described in 1862<sup>(1)</sup>. Cerebral palsy was known as Little's disease for decades. The term cerebral palsy originated in 1893<sup>(2)</sup>.

CP is an “umbrella term” covering a wide variety of clinical conditions that meet 4 criteria:

- Presence of a disorder of movement or posture
- Secondary to a cerebral abnormality
- Arising early in development
- By the time movement impairment exists, the cerebral abnormality is static<sup>(3)</sup>.

There is no test, genetic, metabolic, immunologic, or otherwise, that demonstrates the existence or absence of CP because there is no specified cause, cerebral pathology, or even type of motor impairment-only that motor impairment exists resulting from non progressive cerebral pathology acquired early in life. It is not a single disease. Even as a clinical description these criteria fail in several aspects to achieve the precision required of a definition<sup>(4)</sup>.

The 4 criteria cannot be addressed until (a) motor development can be clearly recognized as being normal or

disordered, and (b) the possibility of progressive cerebral disease can be excluded. Signs suggesting disordered motor control may be recognized very early in life, but accurate prediction has only been confirmed by trained observers in the small proportion of persons with CP born very preterm<sup>(3)</sup>.

The Gross Motor Function Classification Score (GMFCS) categorizes youths and children with cerebral palsy. This system classifies patients into 5 levels based on self-initiated motor function:

- **Level I:** walks without limitation
- **Level II:** walks with limitations
- **Level III:** walks using a hand-held mobility device
- **Level IV:** self-mobility with limitations; may use power device
- **Level V:** transported in manual wheelchair <sup>(5)</sup>.

Equinus and hip displacement are the two most common musculoskeletal deformities found in children with cerebral palsy<sup>(6)</sup>.

In patients with severe cerebral palsy, hip displacement is often diagnosed late as a result of the silent nature of the displacement, communication difficulties, and the increased attention paid to other important issues such as feeding difficulties and seizure management<sup>(6)</sup>.

Identifying the subset of patients with an increased risk of hip displacement is essential in planning surveillance programs and early intervention<sup>(6)</sup>.

Screening program for early detection of hip dislocation is very important for good intervention time. The main goal of treatment is to improve efficiency of gait or to improve postural problems and pain to ensure accepted life and good hygienic measures. Treatment starting from control of muscle tone up to femoral and pelvic osteotomies to ensure normal placement of femoral head and prevent further dislocation<sup>(4)</sup>.

Changes that affect muscle tone lead to imbalance between hip flexors and extensors, increased tone in hip flexors and adductors cause femoral head to start migration till full dislocation. It is important to know that these patients usually have normal hip at birth and the problem of dislocation starts gradually with progression of the problem. Normal development of both femoral head and acetabulum are greatly affected<sup>(6)</sup>.

Diagnosis of hip dislocation in cerebral palsy depends on history and clinical assessment including muscle tone, ROM, bone deformity, examination of hip and knee, scoliosis.<sup>(7)</sup>

Radiological assessment including plain x-ray: anteroposterior plain x-ray of pelvis is very important to assess degree of MP of femoral head in relation to acetabulum<sup>(7)</sup>

CT is used mainly to assess the direction of hip dislocation especially 3D reconstruction form.<sup>(7)</sup>

The hip treatment is then divided into three categories prevention, reconstruction, palliative. **The first** is prevention, which depend manily on managing the cause of dislocation including adductor lengthening considered the first line of preventive treamen. The high-risk period for the development of hip subluxation is from the ages of 2 to 6 years<sup>(7)</sup>. Other historical lines of preventive measures are iliopsoas transfer, adductor transfer etc. <sup>(8)</sup>.

**The second** is reconstruction, The goal of reconstruction is to leave children with an anatomically normal hip joint, with normal posture and normal range of motion, in which the treatment is primarily directed at reducing the femoral head into the appropriate place in the acetabulum, followed by reconstruction of the acetabulum to correct its bony deformity.<sup>(7)</sup>.

**The third** is palliative, in which the goals of treatment are to do a resection procedure of the severely deformed joint to remove the source of pain and/or improve the function or range of motion<sup>(7)</sup>.

## **AIM OF THE ESSAY**

The aim of this essay is to review the literature regarding hip pathology in cerebral palsy, as well as, the management of hip dislocation in spastic cerebral palsy patients.

*Chapter (1):***HIP PATHOLOGY IN CP**

The hip joint is the largest joint in the body and is the joint that causes the most problems both from a functional perspective and at the level of walking, sitting, and lying in children with cerebral palsy (CP). Hips in children with CP are normal at birth, and the problems develop slowly as the children grow and deform under the influence of abnormal forces caused by hypertonia. A second group of children with CP do not actually develop deformity; however, the infantile shape of their proximal femur does not resolve because there is not enough normal force present. After addressing the concerns of equinus contractures in children with CP, hip problems are the next main area of interest to orthopaedists treating these children.<sup>(9)</sup>

**Spastic Hips:**

Hip problems in children with CP first need to be divided by children's type of tone into either spastic children or those children who are hypotonic. The spastic group should also include children with movement disorders such as athetosis and dystonia. The hypertonic hips can be subdivided further by the direction of the dysplasia or the abnormal force into posterosuperior, anterior, inferior and, additionally, by several contracture patterns that may be independent of or concurrent with dysplastic hips. These contracture patterns include

windblown hips and hyperabducted hips. The hypotonic hips in children with CP are a little more diffuse and are harder to further categorize.<sup>(9)</sup>

### **Posterosuperior Hip dislocation:**

The most common dysplastic hip problems in children with hypertonia or spasticity are posterosuperior hip subluxation, dislocation, or dysplasia.<sup>(10)</sup> These problems comprise the typical spastic hip dysplasia (SHD), which is discussed in most of the literature. Based on an extensive review by Cooke, in which attention was paid to the specific pattern of dislocation, 91% to 92% of spastic children with hip subluxation or dislocation have this typical posterosuperior pattern.<sup>(10)</sup>

### **Etiology & Primary pathology:**

The etiology of spastic hip disease has been worked out fairly clearly both through clinical review and, more importantly, through modeling.<sup>(11,12)</sup> The concept of an abnormal force caused by adductor muscles was first suggested in a paper by Keats<sup>(13)</sup> and was the basis upon which he advocated doing adductor lengthening to prevent the spastic hip at risk from dislocating. Since that time, there have been many other clinical studies in which different primary etiologies for spastic hip disease were presented. These etiologies include femoral neck valgus as a primary cause<sup>(14,15)</sup>, and in one study, the femoral valgus was believed to be the direct cause of the
