SUMMARY

Meningitis; is an inflammation of the membranes that surround the brain and spinal cord, thereby involving the arachnoid, the pia mater, and the interposed cerebrospinal fluid (CSF).

The meningitis syndrome may be caused by a variety of infectious agents, as well as non infectious diseases and other etiologies.

There are some risk factors that predispose the individual to meningitis. Host risk factors can be grouped into four categories: age, demographic/socioeconomic factors, exposure to pathogens, and immunosuppressant.

Immunodeficiency increase risk for bacterial meningitis whether primary or secondary immune deficiency. The absence of an opsonic or bactericidal antibody is a major risk factor in most cases of meningitis caused by group B streptococcus, E coli, Hib, S pneumoniae, and N meningitides.

The goal of the study to estimate the frequency of complement deficiencies in pediatric patients with meningitis, allowing early diagnosis and rapid treatment.

In this study we used CH50 assay as an effective screening test for a complete deficiency of component of the

Acknowledgment

First and foremost, I feel always in debted to **Allah** the most Merciful the most Gracious. Thanks to Allah who has lightened my path to become a humbled student to a noble profession and granted me the ability to accomplish this work.

I would like to express my sincere thanks and deep appreciation to **Prof. Dr. Zeinab Awad Elsaid** Professor of Pediatrics Ain Shams University; for her support and interest. My deep feeling of gratitude goes to her for close supervision, constructive guidance and meticulous revision of the thesis.

I am profoundly grateful to **Prof. Dr. Amal Ahmed Abbas** **Professor** of clinical pathology Ain Shams University for her guidance, valuable comments and careful supervision.

My sincere thanks go to **Dr. Reem Ahmed Elfeiky** Lecturer of pediatrics Ain Shams University; for her kind supervision, tremendous support and faithful guidance.

I am forever grateful to all **My Professors and Colleagues**. I owe them very much for their constant support, advice, and encouragement throughout my work.

Last but not least, no words ever spoken can express my feeling of admiration, love and extreme thanks to **My Family**. Without their help, support and sacrifice, this work could not have seen light.

INTRODUCTION

Bacterial meningitis, an inflammation of the meninges affecting the pia, arachnoids, and subarachnoid space that happens in response to bacteria and bacterial products, continues to be an important cause of mortality and morbidity in neonates and children (*de Louvois et al., 2005*).

In the United States, the overall incidence of bacterial meningitis is about 2 to 10 cases per 100,000 populations per year (*Lavoie and Caucier, 2006*). The incidence is greatest in pediatric patients, especially infants, with attack rates in neonates at about 400 per 100,000. While In Japan, the incidence rate of bacterial meningitis is estimated to be between 10 and 13 per 100,000 in children aged less than 5 years (*Loring, 2004*).

Predisposing factors for bacterial meningitis can be broadly categorized into congenital and acquired conditions and further divided into anatomical abnormalities, immune-deficiencies, and chronic para-meningeal infections. Complement deficiencies are generally associated with an increased risk of bacterial infections but have also been linked to autoimmune disorders, because Complement plays a particularly important role in the defense against encapsulated bacteria including *Neisseria meningitidis*, *Neisseria*

gonorrhoeae, S pneumoniae, and H influenza (*Truedsson et al., 2007*).

Complement deficiency is a form of primary immunodeficiency disorder; deficiency in any component of the complement system can lead to immune-compromise and overwhelming infection and sepsis, deficiency can be inherited or acquired and complete or partial (*Agrawal et al., 2006*). Complement deficiencies form about 2 % of all primary immunodeficiency disorders (*Sjoholm et al., 2006*).

The CH₅₀ assay is an effective screening test for a complete deficiency of component of the classical pathway. Complete deficiency generally yields a very low or undetectable CH₅₀ (*Khajooe et al., 2003*).

The management of complement deficient patients involves education of the patient in vigilance for early signs of infection and vaccination against the organisms to which the patient is susceptible (*Mehta et al., 2010*).

AIM OF THE WORK

The work aims to assess the frequency of complement deficiencies among pediatric patients with bacterial meningitis. Allows recognition of such a risk factor paves the way for proper diagnosis and prompt treatment.
