ACKNOWLEDGMENT

**“First and Foremost, Thanks are Due to GOD,
The Beneficent and Merciful of All”**

It was an honor to work under the supervision of eminent professors, who gave me their whole hearted support and immense facilities as is their usual with their juniors. I owe them more than words can say.

I would like to express my deepest gratitude and sincere thanks to **Dr. Hassan Ahmad El Garem**, professor of Tropical Medicine, Faculty of Medicine, Cairo University, for instructive supervision, continuous guidance, valuable instructions, for offering all facilities for the completion of this work, and for giving me the opportunity to share in this project which is **supported by grant from Cairo University**.

My thanks and appreciation to **Dr. MohyEldienAtia**, Assistant professor of Tropical Medicine, Theodor Bilharz Research Institute, for his strict supervision and advice.

Many thanks to **Dr. Hanan Abdel Elhafez Hamed**, Lecturer of Tropical Medicine, Faculty of Medicine, Cairo University, for her continuous help, valuable suggestions, guidance and encouragement during the progress of this work. I would like to thank her for the meticulous and patient revision of the work.

Whatever I say or write, I will never be able to express my deep feelings and profound gratitude to **Prof. Dr. Hisham Rafaat Elkhayat**, Professor of tropical medicine, Theodor Bilharz Research Institute for

giving me the time to finish my work and his continuous support and advice.

Many thanks to **Dr.Mona Salah EldienHamdy** Professor of Clinical pathology, faculty of medicine Cairouniversity, for offering all facilities for the laboratory work, standardization and interpretation of the results.

I am extremely grateful to **Dr.Wafaa Ahmad Elakel**, consultant of hepatology faculty of medicine Cairo university For her unlimited help in the statistical analysis of the data; she gave me much of her time advice and effort throughout this work.

Many thanks to both **Dr. Tamer Elbaz** lecture of tropical medicine, faculty of medicine Cairo university and **Dr.EkramHamed** professor of interventional radiology National Cancer Institute Cairo university , all my friends, my colleague and patients for their effort and continuous help in collecting liver biopsies.

Finally, no words can express my deepest appreciation and gratitude to my family for their never ending support and care.

2011

ABSTRACT

Hepatocellular carcinoma (HCC) is one of the most common malignancies worldwide and it is one of the major causes of death. HCC is now a rather common malignancy in Egypt which usually develops on top of liver cirrhosis secondary to viral infection.

AIM: To determine the expression profile of two candidate biomarkers (SERPINI1, and QP-C) in the liver biopsy in patients with primary HCC and to compare their expression in patients with HCV whether they are cirrhotic or not and in normal subjects

METHODS: This study was conducted on 21 patients with **HCC** using triphasic computerized tomography (CT) scan and histopathological assessment (when needed) and **24** cirrhotic patients with no evidence of HCC; as well as **25 HCV non** cirrhotic and **7** healthy subjects who served as control group.

We determined the level of (SERPINI1 and QP-C) for all cases together with full clinical assessment, liver biochemical profile, viral markers, conventional ultrasound (US), abdominal triphasic CT scan and guided liver biopsy for HCC cases with atypical CT pattern.

RESULTS: we found that SERPINI1 and QP-C is highly expressed in HCC group than cirrhotic group with sensitivity and specificity within 80% and 70% respectively for SERPINI1 and sensitivity and specificity within 65% and 79% respectively for QP-C

CONCLUSION: Tissue marker SERPINI1 and QP-C is highly expressed in HCC and so their use as independent tumor marker in the diagnosis of HCC is to be considered

Keywords:

- Hepatocellular carcinoma (HCC) – (SERPINI1)-(QP-C)-(HCV)

INTROUDUCTION

HCC is one of the most common and aggressive cancers worldwide. It has been the third cancer killer worldwide and the second cancer killer China since 1990s (**Yang et al., 2005**).

Globally, the 5-year survival rate of HCC is <5% and ~598,000 HCC patients die each year (**Parkin et al., 2005**).

The high mortality associated with this disease is mainly attributed to the inability to diagnose HCC patients at an early stage. In fact, most symptomatic HCC patients are diagnosed at an advanced stage, thus precluding their chance for surgical intervention (**Yuen et al., 2000**).

In contrast, HCC patients who were diagnosed at an early stage and received curative resection had a significantly improved survival time(**Poon et al ., 2002**)

Detection of, α -fetoprotein (AFP) in the serum of HCC patients in 1970s, has been the only serologic marker widely used for diagnosing HCC patients. This marker allows the identification of a small set of HCC patients with smaller tumors, and these patients have a relatively long-term survival rate following curative treatment(**Zhou et al ., 2000**).)Thus, early detection and resection have been generally recognized as the most important factors to achieve long-term survival for HCC patients (**Poon et al ., 2002**)

Presently, the only approach to screen for the presence of HCC in high-risk populations is the combination of serum AFP and ultrasonography (**Nakakura and Choti., 2000**).

However, elevated serum AFP is only observed in about 60% to 70% of HCC patients and, to a lesser extent (33-65%), in patients with smaller HCCs (**Johnson., 2001**)

Moreover, nonspecific elevation of serum AFP has been found in 15% to 58% of patients with chronic hepatitis and 11% to 47% of patients with liver cirrhosis (**Kim et al., 2004**).

Therefore, it is necessary to identify new serologic HCC biomarkers that have a sufficient sensitivity and specificity for the diagnosis of HCC patients, especially in AFP-normal and/or smaller HCC cases. A significant increase in the expression of the candidate genes ((i.e., **SERPINI1, and QP-C,**) could be detected in most of the HCC samples, including those with normal serum AFP and small tumors.(**Jia., 2007**)

AIM OF THE WORK

To determine the expression profile of two candidate biomarkers (SERPINI1, and QP-C) in the liver biopsy in patients with HCC on top of liver cirrhosis and to compare their expression in patients with HCV whether they are cirrhotic or not as well as in normal subjects.

EPIDEMIOLOGY OF HEPATOCELLULAR CARCINOMA

Hepatocellular carcinoma (HCC) represents approximately 85-90% of primary malignant tumors of the liver (*El Serag and Rudolph, 2007*). It is the fifth most common cancer worldwide and the third most common cancer in mortality (*Parkin, 2001*).

- **Global incidence of hepatocellular carcinoma:**

Liver cancer burden is not distributed evenly throughout the world. Most HCC cases (more than 80%) occur in either sub-Saharan Africa or in Eastern Asia. China alone accounts for more than 50% of the world's cases. North and South America, Northern Europe, and Oceania are low-rate (less than 5.0/100,000) areas for liver cancer among most populations. (*El Serag and Rudolph, 2007*).

An exception to the predominance of HCC among primary liver cancer is the Khon-Kaen region of Thailand, which has one of the world's highest rates of liver cancer (annual age-standardized incidence rate during 1993 to 1997 men, 88.0/100,000; women, 35.4/100,000) (*Parkin, 2002*). However, because of endemic infestation with liver flukes, the major type of liver cancer in this region is intrahepatic cholangiocarcinoma rather than HCC (*Okuda et al., 2002*).

- **Incidence of hepatocellular carcinoma in Egypt:**

HCC is now a rather common malignancy in Egypt, which usually develops on top of liver cirrhosis of viral origin. Both hepatitis C virus (HCV) & hepatitis B virus (HBV) infections increased the risk of HCC in

Egyptian patients. Because of the high prevalence rate of HCV in cirrhotic Egyptian patients, it accounts for most HCC cases in Egypt (**Hassan et al., 2001**). Over a decade (1993-2002), there was nearly a twofold increase of the proportion of HCC among chronic liver disease (CLD) patients in Egypt with a significant decline of HBV and slight increase of HCV as risk factors (**El-Zayadi et al., 2005**).

Sex distribution

In almost all populations, males have higher liver cancer rates than females, with male: female ratios usually averaging between 2:1 and 4:1. At present, the largest discrepancies in rates (more than 4:1) are found in medium-risk European populations (**El Serag and Rudolph, 2007**).

The reasons for higher rates of liver cancer in males may be related to differences in exposure to risk factors. Men are more likely to be infected with HBV and HCV, consume alcohol, smoke cigarettes, and have increased iron stores. However, experiments show a 2- to 8-fold increase in HCC development in male mice; these data support the hypothesis that androgens influence HCC progression rather than sex-specific exposure to risk factors (**Rudolph et al., 2000**).

Age distribution

The global age distribution of HCC varies by region, incidence rate, sex, and, possibly, by etiology. In almost all areas, female rates peak in the age group 5 years older than the peak age group for males. In low-risk populations (e.g., United States, Canada, and United Kingdom), the highest age-specific rates occur among persons aged 75 and older. A similar pattern is seen among most high-risk Asian populations (e.g., Hong Kong
