

Assessment of Mental Health and Quality of Life in Patients with Coronary Artery Bypass Graft

A Proposal

Submitted for fulfillment of Masters degree in neuropsychiatry

Faculty of Medicine - Cairo university

By

Mohamed Abd El-Monim Mohamed Farghaly
M.B.B.CH.

Supervised by

Prof . Dr. Samia Abd-Elrahman Ahmed

Professor of psychiatry

Faculty of medicine

Cairo University.

Prof .Dr. Mohamed Ezzat Amin

Professor of psychiatry

Faculty of medicine

Cairo University.

2012

Acknowledgements

I am deeply grateful for the support and constructive guidance of many people, whose valuable assistance made this study possible.

First and foremost, I am deeply indebted to. **Prof. Samia Abd-Elrahman**, Professor of Psychiatry; Faculty of Medicine, Cairo University for her deep interest in the subject and valuable comments. I very much appreciate her wisdom, continuous support and immediate help in every step of this work. It is a great honour to work under her guidance and supervision, as well as a unique learning experience.

I would like to express my profound gratitude to **Ass. Prof. Mohamed Ezzat**, Assistant Professor of Psychiatry, Faculty of Medicine, Cairo University. Without his enthusiastic encouragement, inspiring guidance, and valuable supervision this work would not have been possible. It was a great and unique learning experience. And it is a true honour to work under his supervision.

I would like to express my deep thanks and appreciation to **Ass. Prof. Ahmed Eldayan**, Assistant Professor of Cardiosurgery, Cairo University, for his kind support in this study, scrutiny, valuable instructions and advice throughout the work.

No words can express my gratitude to **Prof. Emad Hamdy**,

and Prof. Noha Sabry, professors of Psychiatry, Faculty of Medicine, Cairo University, for their generous help and support for this work.

I wish to extend my thanks to **Dr. Mohamed Abdel-Fattah**, assistant lecturer of psychiatry, Cairo University for his valuable help, and advice.

Dedication

I would like to dedicate this work to the soul of my father, who has been the source of support, guidance and encouragement throughout my life.

Also, I would like to express my deep thanks to *my mother, sister* for their help, support and encouragement and care.

Last, but not least I would like to express my deep gratitude to *my dear wife* for her continuous support, help and encouragement all through this work.

Literature Review

Introduction:

Mental health and Quality of life are affected by coronary artery disease to varying extents. Coronary-artery bypass grafting (CABG) is the surgical procedure used to treat coronary artery disease to alleviate the physical burden of the illness and improve the patient's daily performance. It is expected that the quality of life for CABG patients will improve after a successful CABG procedure. A growing consensus finds it crucial to consider quality of-life (QOL) measures when assessing the value of medical procedures (Prevost et al, 1993). In general thoracic surgery, postoperative psychiatric disorders (PPDs) are associated with adverse outcomes including a longer hospital stay, and increased morbidity and mortality rates (Mehmet et al , 2009).

CABG surgery results in improved QOL for the majority of patients with extensive coronary artery disease. Nevertheless, some patients continue to have severe pain, sleep disturbances, and altered relationship with their spouse or next of a kind, 12 months after surgery (Hunt et al, 2000).

Fifteen percent of patients scored as probable cases of anxiety or depression. They were more likely than non-cases to report pre-infarct distress and poor adjustment (as indicated on the 36-item Medical Outcome Study short form),(Mayou et al 2000).

Elevated anxiety scores have been reported for 20% to 55% (Lavie and Milani 2004).

There is a prospective demonstration of a relationship between presurgical depressive symptoms and post-CABG mortality. And treating depression or depressive symptoms in CABG patients may have impact on quality of life, medical outcomes, and longer-term survival (Matthew et al 2003).

Depression is an important independent risk factor for cardiac events after CABG surgery (Connerney et al 2001).

Postoperative cognitive decline may diminish improvements in QOL. Strategies to reduce cognitive decline may allow patients to achieve the maximum improvement in QOL afforded by CABG, as even short-term cognitive dysfunction has implications for QOL 1 year later (Phillips et al 2006)

Cognitive impairment seems to be strongly associated with Cardio Pulmonary bypass and the occurrence of micro emboli. The off-pump technique appears to be promising in order to eliminate the source of these neuropsychological impairments following CABG operation (Diegeler et al 2000).

A population-based case-control study suggests that coronary artery bypass grafting is not a major risk factor for dementia overall, or for Alzheimer disease (Knopman et al 2005)

In a longitudinal assessment of neurocognitive function after coronary-artery bypass surgery, there were results that confirm the relatively high prevalence and persistence of cognitive decline after CABG and suggest a pattern of early improvement followed by a later decline that is predicted by the presence of early postoperative cognitive decline (Newman et al 2001).

Assessment of anxiety and depression together with evaluation of QOL, in addition to psychiatric evaluation will be used to explore the quality of life for patients experienced after CABG cardiac surgery.

Aim of work:

The aim of this thesis is to study the effect of CABG procedure on mental health and quality of life in CABG patients, two months after the operation.

THE RELATION OF MENTAL HEALTH
WITH CAD AND CABG

What is mental health?

Mental health is not just the absence of mental disorder. It is defined as a state of well-being in which every individual realizes his or her own potential, can cope with the normal stresses of life, can work productively and fruitfully, and is able to make a contribution to her or his community (Richard, J 1995).

About 14% of the global burden of disease has been attributed to neuropsychiatric disorders, mostly due to the chronically disabling nature of depression and other common mental disorders. Such estimates have drawn attention to the importance of mental disorders for public health. However, because these estimates stress the separate contributions of mental and physical disorders to disability and mortality, they might have entrenched the alienation of mental health from mainstream efforts to improve health and reduce poverty. The burden of mental disorders is likely to have been underestimated because of inadequate appreciation of the connectedness between mental illness and other health conditions.

Because these interactions are protean, there can be no health without mental health. Mental disorders increase risk for communicable and non-communicable diseases, and contribute to unintentional and intentional injury. Conversely, many health conditions increase the risk for mental disorder, and comorbidity complicates help-seeking, diagnosis, and treatment, and influences prognosis (Prince, M et al 2007)

It is possible to imagine that worse physical health status could affect mental health. Similarly, worse mental health status can be associated with worse physical health status, as is found in conditions such as depression, where patients may have heightened perceptions of physical limitation. On the other hand, the baseline HRQL is a major determinant of postoperative HRQL as well as mortality (Herlitz J et al 1999), (Curtis LH et al 2002).

Dispositional optimism as a personality resource can have an important role in the response to recovery from CABG (Blumenthal and Mark 1994). Furthermore, preoperative denial was an adaptive
