# **UPDATES IN Hepato-Biliary Injuries**

*Essay*

*Submitted For Partial Fulfillment of Master  
Degree*

*In General Surgery*

*By*

**Mahmoud Saad Ibrahim El-Shenawy**

*M.B.B.Ch.;*

*Under Supervision of*

*Prof. Dr.*

**Mohamed Ahmad Khalaf-Allah**

Professor of General Surgery  
Faculty of Medicine, Ain Shams University

***Dr. Ahmed Gamal Eldin Othman***

Lecturer of General Surgery  
Faculty of Medicine, Ain Shams University

***Dr. Mohamed Abd Elstar Abd Elhamed***

Lecturer of General Surgery  
Faculty of Medicine, Ain Shams University

**Ain Shams University  
Faculty of Medicine**

**- 2017 -**

بِسْمِ اللَّهِ الرَّحْمَنِ الرَّحِيمِ

# وقل اعملوا

## فسيري الله عملكم

### ورسوله والمؤمنون

صدق الله العظيم

سورة التوبه آيه ١٠٥

## Acknowledgments

*First and foremost, I feel always indebted to Allah the Most Beneficent and Merciful.*

*It is a great honor to me to express my deepest gratitude and appreciation to **Prof. Dr. Mohamed Ahmad Khalaf-Allah**, Professor of General Surgery, Ain Shams University, His valuable support, precious advice, continuous encouragement and constructive guidance were the most driving forces in the initiation and progress of this work.*

*I would like to express my sincere appreciation and my deep gratitude to **Dr. Ahmed Gamal Eldin Othman**, & **Dr. Mohamed Abd Elsatar Abd Elhamed** Lecturer of General Surgery, Ain Shams University for his faithful supervision and guidance.*

*Candidate*

**Mahmoud Saad Ibrahim El-Shenawy**

<b>Figure (31)</b>	Images during endoscopic retrograde cholangiopancreatography (ERCP) carried out on a 12-year-old boy with spinal, chest, and abdominal injuries who was noted to have bilious fluid draining from his chest tube (biliothorax) showing: a the appearance as contrast was being injected; b a bile leak from the subsegmental biliary pedicle and a biliopleural fistula; c a stent in situ.	<b>64</b>
<b>Figure (32)</b>	Cholangiogram showing CBD stricture	<b>66</b>
<b>Figure (33)</b>	A, B Hepatic angiograms of a 28-year-old man after blunt abdominal trauma show a large aneurysm (arrow) fed by the middle hepatic artery (arrowhead). C It was superselectively embolized using steel coils with minimal sacrifice of other branches. There is filling of the aneurysm (D, star) and a steel coil is visible (E, arrowhead) on pre- and 3-months postembolization CT images.	<b>70</b>
<b>Figure (34)</b>	Diagnostic algorithm to patients with blunt hepatic trauma.	<b>75</b>
<b>Figure (35)</b>	A 42-year-old woman with hemobilia after open cholecystectomy done 2 months previously shows a right hepatic artery aneurysm (arrow) on (A) CT and (B, inset) hepatic angiogram. It was embolized with steel coils (B, arrow). C Four months after embolization, unenhanced CT shows an aneurysm packed with coils (arrow). D There is no enhancement of the aneurysm on contrast-enhanced CT.	<b>93</b>
<b>Figure (36)</b>	Manual compression of severe liver injury over laparotomy pads as resuscitation is taken place	<b>104</b>

# Introduction

## Introduction

Blunt hepatic injury remains a frequent intra-abdominal injury in the adult trauma population. The management of blunt hepatic injury has undergone a major paradigm shift from mandatory operative exploration to non-operative management. Hemodynamic instability with a positive focused abdominal sonography for trauma and peritonitis are indications for emergent operative intervention. Although surgical intervention for blunt hepatic trauma is not as common as in years past, it is imperative that the current trauma surgeon be familiar with the surgical skill set to manage complex hepatic injuries (*Kozar et al., 2010*).

The management of blunt hepatic injury has considerably changed. Three options are available as follows: nonoperative management (NOM), transarterial embolization (TAE) and surgery (*Melloul, et. al., 2015*).

A high complication rate following high-grade liver injuries should be anticipated. In patients with clinical evidence of biliary complication, CT scan is a useful diagnostic and therapeutic tool. ERCP and temporary internal stenting, together with percutaneous drainage of intra-abdominal or intra-hepatic bile collection, represents a safe and effective strategy for the management of

---

complications following both blunt and penetrating hepatic trauma (*Gazalla Bala, et. al., 2012*).

Bile leaks are a frequent complication in the non-operative management of liver injuries, occurring in 6% to 20% of cases. Majority of bile leaks can be treated by ultrasound or CT-guided percutaneous drainage or ERCP and stenting. (*Jagad, R., et. al., 2013*).

Injury to the extrahepatic biliary tract occurs frequently due to damage inflicted during upper abdominal operations, cholecystectomy being the commonest situation followed by other upper abdominal surgeries, and less often due to blunt or penetrating abdominal injury. Identification and management of biliary tract injuries demand precise judgement, expertise, timely and appropriate intervention and prevention of complications. Such injuries often require staged surgeries, i.e. drainage as an initial damage control procedure followed by definitive reconstructive surgery (*Chaudhary, et. al., 2015*).

Calot's triangle is an important anatomical and surgical landmark of great importance in surgical procedure of laparoscopic cholecystectomy as well as open cholecystectomy. Only about 25% of major bile duct injuries are recognized at the time of operation. Most commonly, intraoperative bile leakage, recognition of the

---

correct anatomy, and an abnormal cholangiogram lead to the diagnosis of a bile duct injury. More than half of patients with biliary injury will present within the first postoperative month. All these injuries are invariably fatal and can be avoided by meticulous dissection and knowledge of normal anatomy and variations in anatomy around the area of Calot's triangle. (*Khanday S, et. al., 2013*).

Biliary leakages and bile duct stricture are the most severe complication after cholecystectomy, it is usually an early complication whereas biliary strictures are considered as late complication. Investigating biliary leakage, laboratory parameters including: serum bilirubin, serum alkaline phosphatase, serum gamma glutamyltransferase and leucocytic count, are to be determined, also radiological investigations such as laparoscopic ultrasound and intraoperative cholangiography are very useful (*Weber, et. al., 2009*).

Prevention of bile duct injury, technique has been developed for intraoperative assessment of bile duct anatomy. The critical-view-of-safety approach should be used during laparoscopic cholecystectomy intraoperative cholangiography or laparoscopic ultrasound is recommended to be performed routinely. Hyperspectral cholangiography and near-infrared fluorescence cholangiography are promising novel technique

---

to prevent bile duct injury and increase patient safety (*Buddingh KT, et al., 2011*).

Currently, standard management of patients with suspected biliary leak after cholecystectomy remains to be determined and both clinical and imaging findings are taken into account in these patients. Also in an emergency setting non-invasive imaging would be ideal for planning further management (*Cantu P, et al., 2011*).

# **Aim Of The Work**
