# Acknowledgement

I wish to express my sincere gratitude to **Prof. Dr. Ashraf Mohamed Hedayet**, Professor of general and vascular surgery, Faculty of medicine, Cairo University for his continuous encouragement, help and kind guidance

I feel very grateful to **Prof. Dr. Hassan Ahmed Soliman**, Professor of general and vascular surgery, Faculty of medicine, Cairo University for his kind and enormous help and guidance during the preparing of this work

**This** work could not have been presented without the help and guidance of **Dr . Amr Mohamed Ahmed Abdelbaky**, Lecturer of general and vascular surgery, Faculty of medicine ,Cairo University

**Also** I would like to express my sincere gratitude to all those who in one way or another taught, coached, guided, encouraged and most important, corrected me in whole my years of education and learning in the faculty of medicine whose influence guided my way in life and career to the extend that I can not find words to thank them with

# **Abstract**

PTA(percutaneous transluminal angioplasty) is the treatment of choice in patients with infrapopliteal occlusive disease who typically present with CLI(critical limb ischaemia). With recent advances in technology, long and multiple stenotic and occlusive lesions can be treated successfully. This minimally invasive procedure carries a lower morbidity and mortality and shorter hospital stay compared with surgery and should be the first treatment option in all patients with CLI who would otherwise be offered distal bypass surgery or amputation, as failure rarely precludes surgery. Clinical success is superior to angiographic patency and in the majority of cases repeat angioplasty can be performed if there is recurrence of ischaemic symptoms and signs.ABI(Ankle-Brachial Index)is a good indexand investigation. Infrapopliteal PTA can also be performed after femoral angioplasty or bypass surgery, to improve outflow and hence patency of the proximally treated segment.

Key wards:

PTA=(percutaneous transluminal angioplasty)

CLI=(critical limb ischaemia)

ABI=(Ankle-Brachial Index)

# **Introduction:**

## **Introduction:**

Currently the most common access methods of infrapopletial angioplasty are contralateral ,antegrade, ipsilateral, and rarely retrograde tibial access . Contralateral approach is the most commonly used method.Its advantages are that it allows for sufficient free movement during procedure., contrast injection is allowed to be closer to the region of interest and during hemostasis, antegrade flow down the treated vessel is not impaired. In patients with an occluded iliac artery or previous aortoiliac reconstruction antegrade approach is preferred. The retrograde tibial access is used when antegrade, contralateral, retrograde methods, have been unsuccessful . Bivalirudin and Tirofiban combination is safe alternative to unfractionated heparine during the procedure .( **Tsetis et al.,2004**)

Balloon angioplasty has been used as the main revascularization modality in chronic limb ischaemia . Cutting balloon in infra popletial arteries was associated with 20% rate of dissection necessitating use of adjunctive stenting . Cryoplasty by using nitrous oxide: the balloon is cooled to under ten degrees resulting in more controlled angioplasty and less need for stenting and less restenosis.Stenting are commonly used in infrapopletial region due to flow limiting dissection and vascular recoil. The use of drug eluting stents in infra popletial region has been compared to bare metal ones with 92% vs. 68% six months patency . Future technology may address the problem of stent restenosis by using bioabsorbable stents with drug eluting capability .The excimer LASER moves plaques by photo acoustic ablation. It allows for plaque ablation .86% procedural success with the use of excimer LASER was reached in subjects with high risk for surgical intervention . Atherectomy compared to balloon angioplasty results in higher luminal gain without plaque displacement and vessel injury.( **Krankenburg et al.,2005**)

**Aim of the work:**

The aim of this study is to evaluate the outcome results of infrapopliteal angioplasty, to overview methods and techniques, that determine the most suitable way to treat different types of lesions.
