FACULTY OF ENGINEERING  
Computer Engineering and Systems

Opportunistic Routing by efficient task management in wireless sensor  
networks

A Thesis submitted in partial fulfilment of the requirements of the degree of

Master of Science In Electrical Engineering

(Computer Engineering and Systems )

By

**Marwa Mohamed Mohamed Hamdy**

Bachelor of Science In Electrical Engineering

(Computer Engineering and Systems )

Faculty of Engineering, Ain Shams University, 2010

Supervised By

**Prof. Hossam M.A.Fahmy**

**Dr. Dina Samir Hassan**

Cairo - (2016)

# Statement

This thesis is submitted as a partial fulfilment of Master of Science in Electrical Engineering, Faculty of Engineering, Ain shams University.

The author carried out the work included in this thesis, and no part of it has been submitted for a degree or a qualification at any other scientific entity.

**Marwa Mohamed Mohamed Hamdy**

# Researcher Data

Name	: Marwa Mohamed Mohamed Hamdy
Date of birth	: 15/12/1988
Place of birth	: Kuwait
Last academic degree	: B.Sc. in Electrical Engineering
Field of specialization	: Computer and Systems
University issued the degree	: Ain Shams University
Date of issued degree	: June 2010
Current job	: Technical Support Engineer at Arab African International Bank

# Acknowledgment

I would like to express my deepest gratitude to my supervisors Prof. Hossam M.A.Fahmy and Dr. Dina Samir Hassan who introduced me to the field of wireless sensor networks with encouragement and aided me for the preparation of this thesis in an organized manner.

Aside from academic assistance, I would like to express my endless appreciation to the people who were surrounding me throughout my difficult times and supported me to finalize my thesis. Those are my sisters, my friends and family. They provided me with great help and support during the research period.

Most importantly, I would like to thank my parents for showing me the right direction, to help me stay calm in the oddest of the times and keep moving even at times when there was no hope.

Marwa Hamdy

# Thesis Summary

Minimizing energy consumption is a fundamental requirement when deploying wireless sensor networks (WSN's). Accordingly, various control protocols have been proposed, which aim to conserve energy by turning off unnecessary sensors while simultaneously preserving a constant level of routing fidelity. However, although these protocols can generally be integrated with any routing scheme, few of them take specific account of the issues that arise when they are integrated with different routing mechanisms.

Also, in numerous applications of wireless sensor networks (WSN), the reliability of the data collected by sensors is cast as specific Quality of service requirements expressed in terms of the minimum number of sensors needed to perform various tasks. Designing a long- lived sensor network with reliable performance has always been challenging due to the modest nonrenewable energy budget of individual sensors. In such a context, energy-unaware task management protocols may result in uneven expenditure of sensor energy by assigning uneven workloads to sensors. This, in turn, often translates into reduced sensor density around those heavily loaded sensors and may, eventually, lead to the creation of energy holes that partition the network into disconnected islands.

In most of the existing sensor networks, the load is not evenly distributed, making it inefficient in field application. Also, the network unaware uneven node density leads to energy holes depleting faster the network energy. To improve this situation research on energy efficient opportunistic routing (EEOR) has been done earlier which focuses on giving priority to few intermediate forwarder nodes from a set of forwarder list, to transmit the data towards destination. In this research, a novel task

management protocol is proposed that distributes task among nodes based on sensor node energy, geographical position, and intermediate forwarder node priority. The proposed opportunistic routing algorithm is simulated using the OPNET network simulator and various scenarios like effect with node density, mobility, geographical positions are analysed. We compared the overall network end to end delay, traffic statistics, packet delivery ratio achieved by efficient task management and equal load distribution among a group of sensor nodes using the proposed protocols against the priority based EEOR technique. Further, simulation manifests that the proposed approach provides better result than EEOR routing protocol in terms of network delay, traffic received, and energy consumption.

**Key words:** Energy consumption, load balancing, opportunistic routing, task management, wireless sensor networks

# **Chapter 1 Introduction**

## **1.1 Motivation**

Wireless sensor networks (WSNs) are an important and exciting new technology with great potential for improving many current applications in medicine, transportation, agriculture, industrial process control, and numerous future military applications. A wireless sensor network is a network of wireless embedded system elements, which consists of distributed autonomous devices using sensors to cooperatively monitor physical or environmental conditions, such as temperature, sound, vibration, pressure, motion at different locations. Deploying wireless sensor network for real world applications can be beneficial if the sensors nodes operate for longer time duration yielding maximum network efficiency.

## **1.2 State of the Art**

Multi-hopping is the key feature in these networks. The major concerns for protocol design in this area involve energy conservation, scalability due to the large number of nodes, bandwidth, delay and security. Components of a typical wireless sensor node are shown in Figure 1-1. A sensor node has the following components. A sensor unit to perform the basic sensing operations, a memory unit to store the sensed information, a battery for power requirements, a processor

for data processing operations and a transceiver for transmitting and receiving the data. The transceiver unit is provided with a limited range antenna. The memory provided in the sensor node is normally a limited storage memory to facilitate small size, as normally the node is transmitting the data sensed and does not store it. The battery is loaded with an initial energy and has limited life. With these five necessary units, a sensor node can be equipped with optional units such as a mobilizer, location finding unit and power generator.

Figure 1-1 Wireless sensor node components [11]

Wireless sensor networks have their own unique characteristics, which create new challenges for the design of routing protocols for these networks. Sensors are very limited in transmission power, computational capacities, storage capacity and most of all, in energy. So, a vital area of research is to implement methods to achieve and maintain a satisfactory level of application specific QoS. The conventional routing protocols available for wired network works on choosing
