Acknowledgement

I would like to express my sincere thanks, deep gratitude and extreme appreciation to ***Prof. Dr. OMAR EL-SAYED EL-SHOUBAGY***, Professor in Medical Studies Department, Institute of Postgraduate Childhood Studies, Ain Shams University, for his remarkable help, supervision and valuable guidance throughout the work. His constant support and follow-up of the progress of research are really appreciated.

It is a great honor for me to take this chance to express my greatest gratitude to ***Prof. Dr. MAGDI KARAM EL-DIN***, Professor in Medical Studies Department, Institute of Postgraduate Childhood Studies, Ain Shams University, for his kind supervision, and the great help he offered me during the preparation of this work

It is for my great pleasure to express my gratitude and appreciation to ***Prof. Dr. MAISA NASR FARID***, Professor of Pediatrics in Medical Studies Department, Institute of Postgraduate Childhood Studies, Ain Shams University, for her valuable assistance and endless cooperation. Words are not enough to express my appreciation for her continuous support and guidance.

Special thanks and dedication to my ***family***, for their continuous help, support and encouragement during the preparation of this research.

Abstract

"Evaluation of Herbal Nutritional Intervention in Cases of Down Syndrome"

Sameh Ali Hassan ,Omar El-Sayed El-Shorbagy ,Magdi Karam El-Din Ali , Maisa Nasr Farid.

Aim of the study is to evaluate the nutritional intervention and using of phyto-therapy containing some vitamins and minerals to children with Down syndrome by providing optimal nutrition for these children .

Methodology The study included ٣٠ cases with Down syndrome and ٣٠ controls. All subject were subjected to: Complete history, complete medical and neurological examination, IQ , nutritional and language assessment. A program of nutritional herbal intervention was done for the cases for ٦ months.

Results The intervention group showed improvement in blood picture as the percentage of cases who had no hematological disorder increased from ١٣,٣% to ٦٠% after the intervention program. Also there was a significant increase ($P \leq ٠,٠٠١$) in the head circumference, weight, height, mid-arm circumference, body mass index and IQ after the intervention program than before. There was a significant difference ($P \leq ٠,٠٥$) before and after the intervention program as regard the skin fold thickness; height, and body mass index. Cases in the intervention group were improved as regard the speech {language} disorders, before the intervention program ٤٠% complained of no-speech {delayed speech} which decreased to ٣٣% after the intervention program.

Conclusion It could be concluded that children with Down syndrome could be prevented or treated by with the suitable multivitamins mega doses, amino acids, polyunsaturated fatty acids, and trace elements early in childhood is very essential and important for the improvement of the physical and cognitive status of the patient.

Introduction

Children with special health needs must have the opportunity to achieve their potential in all areas of development. Appropriate nutrition services are a critical aspect of the support required for this to occur. Children with special health needs are vulnerable to all of the factors that place other children at nutritional risk, and to a myriad of additional biological, environmental, and psychosocial variables that may further jeopardize their nutritional status and pose barriers to their development. (*Lichtenwalter et al., 1993*).

Down syndrome is characterized as a chromosomal disorder, resulting in mental retardation and physical abnormalities. Persons born with Down syndrome have an extra chromosome, making three of a kind, known as trisomy. Of all Down syndrome cases, 95% are caused by trisomy 21. People with this type of trisomy disorder generally live until their 30s or 40s (*Connors et al., 2001*).

Down syndrome is one of the most frequent congenital multiple handicaps, occurring in one to two a systemic acceleration of the aging process. Research shows that prevention can begin prior to birth. In the American Journal of Clinical Nutrition, it was reported that mothers of children with Down syndrome have genetic and biochemical evidence of abnormal maternal folate metabolism. The FDA's National Center for Toxicological Research (NCTR) now recommends that women start supplementing with folic acid 3 months prior to trying to conceive (*James et al., 1999*).

The physiological and neurological problems of people with Down syndrome may be partially due to the resulting oxidative damage. Antioxidant supplementation may be valuable to Down syndrome patients, and regular tests can help monitor the amount of tissue damage caused by oxidation (*Burger et al., 1993*).

Early studies show that multiple vitamin deficiencies can be present for long periods of time in patients with Down syndrome (*Williams et al., 1989*).

In other studies, children with Down syndrome who were supplemented for the first three years of life with a combination of vitamin B₆ and 5-hydroxytryptophan

improved in social maturity and accomplishment . Down syndrome patients would generally benefit by the daily consumption of a multinutrient formula, to compensate for weak metabolic functioning and the likelihood of malabsorption. Recommended dosage would be just slightly below the adult dosage (*Coleman et al., 1989*).

It is believed that the failure of the brain to develop, especially the hippocampal region (controlling memory), may be caused by vital nutrient deprivation. Proper nutrient assimilation combined with cell therapy has increased brain growth in some Down syndrome patients .Addressing immune dysfunction is a crucial component of any Down syndrome protocol. Simply ensuring proper nutrient assimilation can be very effective at improving host defense mechanisms (*Tyrrell et al., 2001*).

Trisomy 21, more commonly referred to as Down syndrome , it is a genetic disorder which is present in approximately 1 out of every 700 live births. It results in three number 21 chromosomes, as opposed to the normal two .The diagnostic clinical features of this condition are usually readily evident, even at birth. Down syndrome is a leading cause of mental retardation, the mental retardation is severe , virtually all patients with trisomy 21 older than 40 years of age develop neuropathologic changes characteristic of Alzheimer's disease, a degenerative disorder of the brain. Patients with Down syndrome have abnormal immune responses that predispose them to serious infections, particularly of the lungs, to thyroid autoimmunity, and an increased susceptibility to leukemia (*Cotran et al., 1999*) (*Van Dyke et al., 1990*).

Nutrition interventions are often related to feeding, including mechanical and behavioral aspects of the processes by which food is provided and intake occurs. For some children, improved nutrition is the factor most critical for survival, for others it can reduce the potentially debilitating effects of their conditions. (*Cross-McClintic et al., 1994*).

The nutritional status of Special Health Care Needs Children is influenced by a complex of factors that necessitate interdisciplinary interaction for assessment and intervention (*Baer et al., 1991*).

Numerous studies have shown poor lipid metabolism in Down syndrome. Omega 3 and omega 6 fatty acids are decreased . Cholesterol is often increased without a

concomitant increase in cardiovascular risk . Apolipoproteins E is abnormal and may contribute to the increased Alzheimer risk in Down syndrome (*Burger et al., 1998*).

Docosohexaenoic acid (DHA) is decreased in Down syndrome individuals . There is good data to show improvements in brain and retinal development in children supplemented with DHA (*Mann et al., 1990*).

There are many potent antioxidants available in brightly colored fruits and vegetables. The food pigments themselves are often antioxidants. Examples include orange colored “beta-carotene” in carrots and squash ,red “lycopene” in tomatoes and watermelon, green “lutein” in dark leafy greens ,red/blue“anthocyanins” in blueberries and beets, and white/yellow “flavones” in onions and garlic. This class of substances is usually called “phytochemicals”. Many vegetables and fruits have a wide variety of phytochemicals that have benefits in addition to the antioxidant content, so children’s diets should be as generous in these foods as possible . (*Cloud , 2001*).

For thousands of years medicinal plants (Phytotherapy) have been at the core of alleviating human suffering and promoting health and well-being through the use of common plants. (*Benton et al., 1988*).

In recent times, a great deal of emphasis has been placed on the importance of adequate vitamin intake to overall health and the prevention of disease. This emphasis, and preliminary research linking vitamin supplementation to improvements in IQ in non-handicapped school children and mentally retarded children (*Harrell et al., 1981*) have led many parents to administer large doses of vitamins to their children with DS. hoping to maximize their IQ. (*Yudkin, 1991*).

Hypothesis:

Preventive nutrition services, as well as intervention for identified problems, can help assure a well-nourished child who is healthy, can participate in education and therapy programs, and is better able to function in almost all activities of daily life.

Aim of the study:

The aim of the present study is to evaluate the nutritional intervention and the use of phyto-therapy (herbal medicine) containing some vitamins and minerals to children with Down syndrome by providing optimal nutrition for these children .
