Mohammed El Said Hamouda

Researcher Data

Name : Mohammed El Said Hamouda

Date of birth : 15/9/1987

Place of birth : Alexandria – Egypt

Academic Degree : B.Sc in Mechanical engineering.

Field of specialization : Mechanical engineering

University issued the degree : Alexandria University

Date of issued degree : 2009

Current job : Mechanical engineer.

Abstract

Control valve is required to control flow or pressure of fluid flowing in piping systems. In the present work, experimental measurements are reported for flow characteristics of single stage and two stage control valves are reported under non-cavitating and cavitating conditions. A test rig was constructed to test valve performance at the Faculty of Engineering, Ain Shams University. The test rig of the experiment consists of a vertical, multistage inline centrifugal pump driven by variable speed motor, piping system, flow meter, pressure gauges, differential pressure manometer. Water is recirculated to a large water tank 25 m³. Insertion type magnetic flow meter the effects of diameter ratio and spacing between the two stages are examined. Four single stage valves and five alternatives of two stage valves are investigated. The results show that the pressure loss coefficient is inversely proportional to the distance between the two seats in the two stage valves. Cavitation occurrence decreases if the area ratio of the valve is reduced and the distance between the two stages decreased. The inherent characteristics of the valve are also affected by the geometry parameters of the two stage valve.

Keywords: cavitation – two-stage valve – pressure control

Acknowledgment

I would like to express my appreciation to my advisory committee: Prof. Ahmmed EL.Baz and Prof. Abd El.Aziz Morgan, of the Mechanical Power Engineering Department at Ain Shams University for the considerable and valuable amount of advice, guidance and assistance which they gave me during this research work.

My gratitude also goes to Mr. Sherif Abd El monaim, there are not enough words to describe your excellent work. You are the heart and soul of the Fluid machines laboratory.

Special thanks to Eng. Ibraheem ElSageer my manager at my work for giving time to complete this work.

Eng. Abd El.Hameed Salama the mechanical office manager in Alexandria for Construction Company, I am so grateful for the valuable information you gave to me.the most special thanks goes to my Parents and Sisters, you gave me your unconditional support and love through all this long process.

Chapter 1

Introduction

1.1 Introductory Remarks

A control valve plays an important role in a closed pipeline system and is widely used in a variety of industries such as chemical engineering and petrification. Among control valves, a globe valve is commonly used as a flow regulation device under extremely high pressure conditions. For example, the inlet pressure may be higher than 100 bars and from time to time 200 bars. For a globe valve, which conveys liquids, cavitation is a serious and destructive problem during its operation because pressure may drop owing to the variation of velocity according to Bernoulli's equation. The inception of cavitation occurs when the local pressure in a globe valve drops from the increase of velocity and is below the corresponding saturated vapor pressure of a working liquid at a specific temperature. Vapors begin to form in bubbles in low pressure regions and then burst immediately from pressure recovery as they flow downstream, resulting in vibration and erosion. Additionally, this not only causes vibration of the valve body but also induces a high noise level. Because of cavitation, a globe valve is damaged quickly. It is common to replace damaged globe valves in a pipeline system every few months in petroleum industry. Replacing globe valves damaged by cavitation in a factory becomes a regular and costly affair; this is an important issue in the design of a globe valve. Currently, most valve
