## **ACKNOWLEDGEMENT**

In the name of Allah, the most-gracious, the most-merciful, I start my thesis.

I wish to express my deep thanks and gratitude to my dear Professor **DR. MERVAT HASSAN ELNAGGAR**, Prof. of Radiation Oncology, National Cancer Institute, Cairo University, for giving me much of her precious time, for her valuable advices and support and for her meticulous supervision during all the stages of preparation of this work, for which I am deeply indebted.

I would also like to express my deepest gratitude and sincerest thanks to Professor **DR. AHMED SELEEM FOUAD**, Prof. of Clinical Oncology, Faculty of Medicine, Cairo University whose constructive encouragement and help were behind the accomplishment of this work.

Great thanks are also expressed to **DR. MOHAMED MAHMOUD ABDELHAKIM**, Assistant Professor of Radiation Oncology, National Cancer Institute, Cairo University, for his invaluable guidance, enlightening remarks, and endless encouragement all through the steps of this work.

Finally, I can find no enough words to express my deepest gratitude and appreciation to my parents, my wife, and my family, who by their prayers and invaluable assistance, helped me a lot through the stages of this research.

## **ABSTRACT**

**Aim of the study:** To identify all clinico-pathological data, different treatment modalities and the different prognostic factors which affected the locoregional control (LC), disease-free survival (DFS), and overall survival (OS) of Type II endometrial cancer patients

**Patients and methods:** Data of Type II endometrial carcinoma patients who presented to the Radiation Oncology department, National Cancer Institute, Cairo University during the period from (2000-2012) were retrospectively reviewed .

**Results and conclusions:** Multivariate analysis identified stage as an independent prognostic factor for OS & DFS, and age was an independent prognostic factor for DFS and LC. Low pretreatment hemoglobin levels significantly affected OS.

Large and multicentric clinical trials are required to further study this group of patients and define optimum treatment modalities.

**Keywords:** Endometrial carcinoma, Radiotherapy, Chemotherapy

## **Introduction:**

Endometrial cancer is the sixth most common cancer in women worldwide & one of the most frequently occurring female genital cancers, with 320,000 new cases diagnosed in 2012. **(Global cancer Atlas - Globocan- 2012)**

The main risk factor to developing endometrial cancer is prolonged periods of unopposed estrogen. This may be due to nulliparity, late menopause, obesity, polycystic ovarian syndrome (PCOS), hormonal replacement therapy (HRT) or the prolonged use of Tamoxifen. **(Braun et al. 2016)**

The most common presenting symptom is postmenopausal vaginal bleeding (90%). **(Salman et al. 2013)**

Endometrial carcinomas are classified into two major histological subtypes: **(Bokhman et al. 1981).**

**Type I** are tumors of endometrioid histology, these comprise approximately 80 percent of endometrial carcinomas. These tumors typically have a favorable prognosis, are estrogen responsive, and may be preceded by an intraepithelial neoplasm (atypical and/or complex endometrial hyperplasia). **(Albertini et al. 2012)**

**Type II** tumors on the other hand account for 10 to 20 percent of endometrial carcinomas. These include tumors of non-endometrioid histology: serous, clear cell, squamous, transitional cell, and undifferentiated. Uterine carcinosarcomas are also included in this subtype. **(Albertini et al. 2012)**

## Introduction

---

The primary treatment of endometrial carcinoma is surgery. Total Hysterectomy, Bilateral salpingo-oophorectomy (BSO) with or without sampling or removal of pelvic lymph nodes is generally performed. **(Bourgin et al. 2016)**

Patients are then risk stratified according to many factors such as age, stage, grade, histological subtype, and lymphovascular invasion. Providing further adjuvant treatment with radiotherapy / chemotherapy will depend on this risk stratification. **(Colombo et al. 2015)**

### **The Proposed Aim of this work is to:**

- Study the clinical and pathological characteristics of Type II endometrial carcinoma patients.
- Study the patient management and their outcomes.
- Identify the common treatment-related side effects & toxicities.
- Analyze the potential prognostic factors affecting Locoregional Control, Disease-Free Survival and Overall Survival.

### 1.1. Epidemiology:

Endometrial cancer is the sixth most common cancer in women worldwide (fourteenth most common cancer overall), with almost 320,000 new cases diagnosed in 2012 worldwide. **(Global cancer Atlas -Globocan- 2012)**

The global incidence of this cancer was 8.3 women per 100,000 female population in 2012, which represents 4.8% of total cancer incidence. About 1,200,000 women were estimated to be alive with the disease within the last 5 years, ie; the 5 year prevalence of this cancer worldwide was 46.8 women per 100,000 female population in 2012. **(Global cancer Atlas -Globocan- 2012)**

It is estimated that endometrial cancer was the cause of death of 76,000 women worldwide in 2012, a mortality rate of 1.8 women per 100,000 female population. **(Global cancer Atlas -Globocan- 2012)**

According to the National Cancer Registry Program (NCRP) in Egypt, the crude rate of endometrial carcinoma between years 2008-2011 was 0.7 cases per 100,000 females, representing 0.62% of total cancers. The incidence was highest among women above 75 years of age (12.1 cases per 100,000 women). **(Ibrahim et al. 2014)**

According to the cancer pathology registry data at National Cancer Institute (NCI), Cairo University for years 2003-2004, endometrial tumors represented 14.72% of all female cancers and 0.69% of total cancers presented to NCI during the study period. **(Mokhtar et al. 2007)**

Uterine cancer is typically a cancer of postmenopausal women. According to the Surveillance, Epidemiology & End Results (SEER) registry, most cases are
