#### **Summary and conclusion**

Inflammatory bowel disease is a term used mainly to describe two idiopathic disorders that are associated with gastro-intestinal inflammation. Crohn's disease and ulcerative colitis need to be distinguished from other conditions; which may display similar clinical and laboratory findings as infection and neoplasm.

Crohn's disease may involve any portion of the alimentary tract from mouth to anus. Mucosal inflammation may be generalized or patchy, and may extend gradually into the submucosa, muscularis and serosa, which may result in intestinal complications; whereas in ulcerative colitis a homogenous inflammatory process is confined to mucosa and starts in the rectum; but may involve any portion of the alimentary tract as well.

The diagnosis of inflammatory bowel disease is a challenging; as it constitutes a variety of examination techniques that must be performed. Full understanding of the anatomic and pathologic basis of the radiological features of IBD is important to appreciate the natural history and differential diagnosis of these diseases.

Radiological studies have an important role in the diagnosis of patients with suspected IBD and also in the differential diagnosis because of their ability to assess fine mucosal details.

Cross sectional imaging, as CT and MRI, have important role in the evaluation of IBD patients. Double contrast barium studies is a valuable technique in diagnosis of Crohn's disease and ulcerative colitis in patients with early disease; where as cross sectional imaging are valuable for showing the effects of this disease on the wall of the bowel and diagnosis of their intra-abdominal complications in patients with more advanced disease.

Colonoscopy and barium studies can diagnose early manifestations of IBD as erosions, aphthous ulcers and enlarged lymph nodes. MRI can detect variations in bowel wall thickness and contrast enhancement, and it could be the imaging technique of choice for follow up of patients with active IBD due to its lack of the ionizing radiation.

Multi-slice CT allows the diagnosis of Crohn's disease and small bowel masses with 100% sensitivity, 95% specificity, 97% accuracy, 94% positive predictive value and 100% negative predictive value.

With CT colonography, the walls of the bowel segments, which were severely affected by the disease, were illustrated by axial CT scans. Air filled sinus tracts, loss of hausterations, pseudo-polyps and deep ulcers are seen in CT colonography.

## **List of Abbreviations**

2D	Two Dimensional		
3D	Three Dimensional		
AIP	Average Intensity Projection		
CD	Crohn's Disease		
CT	Computed Tomography		
CTA	Computed Tomographic Angiography		
CTDI	Computed Tomography Dose Index		
CTE	CT Enterography		
CTU	Computed Tomographic Urography		
ESR	Erythrocyte Sedimentation Rate		
GISTs	Gastro Intestinal Stromal Tumours		
GIT	Gastro Intestinal Tract		
HRCT	High Resolution Computed Tomography		
HU	Hounsfield Unit		
IBD	Inflammatory Bowel Disease		
IMA	Inferior Mesenteric Artery		
IVC	Inferior Vena Cava		
MDCT	Multi-Detector Computed Tomography		
MinIP	Minimum Intensity Projection		
MIP	Maximum Intensity Projection		
MPR	Multi-Planar Reformatting		
MRC	Magnetic Resonance Colongraphy		
MRI	Magnetic Resonance Imaging		
MSCT	Multi-Slice Computed Tomography		
OGIB	Obscure Gastro Intestinal Bleeding		
PSC	Primary Sclerosing Cholangitis		
ROI	Region Of Interest		
SMA	Superior Mesenteric Artery		
SMV	Superior Mesenteric Vein		
SSD	Shaded Surface Display		
UC	Ulcerative Colitis		
US	Ultra Sonography		
Z-axis	Longitudinal axis of acquisition

	ulcerative colitis	28

#### **Anatomy of small and large Intestine**

#### **Gross Anatomy:**

#### The Small Intestine:

The small intestine is a convoluted tube, extending from the pylorus to the colic valve, where it ends in the large intestine. It is about 7 meters long, and gradually diminishes in size from its commencement to its termination. It is surrounded above and at the sides by the large intestine; a portion of it extends below the superior aperture of the pelvis and lies in front of the rectum. It is in relation, in front, with the greater omentum and abdominal parietes, and is connected to the vertebral column by a fold of peritoneum, the mesentery. The small intestine is divisible into three portions: the duodenum, the jejunum, and the ileum (Gray, 2008).

The Duodenum (Fig. 1-1) is the shortest (25 cm.), the widest, and the most fixed part of the small intestine, and has no mesentery, being only partially covered by peritoneum. Its course presents a remarkable curve, somewhat of the shape of an imperfect circle, so that its termination is not far removed from its starting-point (Gray, 2008).

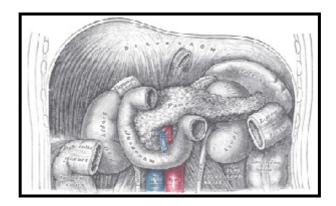

Fig. 1-1: Illustration showing the duodenum and pancreas (Quoted from Gray, 2008).
