2012

ACKNOWLEDGEMENT

I would like to express my utmost gratitude and appreciation to ***Prof. Dr. Magda Samy***, Professor of Ophthalmology, Faculty of Medicine, Ain Shams University, for her sincere encouragement and stimulating views.

I am also faithfully grateful to ***Dr. Sameh Hani***, lecturer of Ophthalmology, Faculty of Medicine, Ain Shams University, for his instructive guidance.

Mohamed Tarek Mohamed

LIST OF FIGURES

| Fig. No. | Title | Page |
|-----------------|--|-------------|
| 1 | Bones sharing in the formation of the orbit. | 4 |
| 2 | The orbit | 5 |
| 3 | The anatomy of the medial orbital wall. Key: ALC, anterior lacrimal crest; LF, lacrimal fossa; PLC, posterior lacrimal crest; LP, lamina papyracea; AEF, anterior ethmoidal foramen; PLF, posterior ethmoidal foramen; OC, optic canal; MES, maxilloethmoid suture. | 8 |
| 4 | Anatomy of the lateral orbital wall, anterior view. Key: GWS, greater wing of sphenoid; SOF, superior orbital fissure; FZS, frontozygomatic suture; FSS, frontosphenoid suture; ZSS, zygomaticosphenoid suture; ZB, zygomatic bone; ZFF, zygomaticofacial foramen; LT, lateral tubercle. | 11 |
| 5 | The orbital rim. | 13 |
| 6 | Openings into the orbital Cavity and structures passing through them. | 15 |
| 7 | Categories of Le Fort fractures. | 22 |
| 8 | Caldwell view showing Blow-out fracture. | 25 |
| 9 | Waters view showing Blow-out fracture. . | 26 |
| 10 | Coronal A) and sagittal B) computed tomography images showing a large fracture of the left orbital floor with herniation of a large volume of orbital fat and a vertically elongated inferior rectus muscle extending to the fracture site. | 27 |

| Fig. No. | Title | Page |
|-----------------|---|-------------|
| 11 | Coronal computed tomographic scan of a trapdoor fracture. | 28 |
| 12 | Sagittal computed tomographic reconstruction showing orbital | 29 |
| 13 | Diagnostic imaging of patient. A, Conventional x-ray view of the midface with the sinus system showing pathologic findings with signs of a left-sided orbital floor fracture with a suspicion of interruption in the continuity of the infraorbital rim and the floor. B, MRI T1- and C, T2-weighting show hematoma (arrows) in the right maxillary sinus below the orbital floor. The integrity of the left orbital floor without any involvement of orbital soft tissue is visible. Inferior rectus muscle remains unaffected in place. | 31 |
| 14 | Measurement of orbital volume on axial scan with tracing | 32 |
| 15 | Measurement of orbital volume on coronal scan with tracing technique. | 33 |
| 16 | A patient with a left orbital floor fracture and inferior rectus entrapment demonstrates restriction of downgaze of the left eye. | 35 |
| 17 | (A) Patient with severe right enophthalmos and hypophthalmos after an injury in a basketball game.(B) Coronal CT scan showing the difference in orbital volume between the two sides. | 37 |
| 18 | Titanium mesh being molded in the operating room using skull. | 44 |

| Fig. No. | Title | Page |
|-----------------|--|-------------|
| 19 | Autogenous bone graft for reconstruction of the orbital floor. (A) Free iliac crest bone graft shaped to match the orbital floor. (B) CT three-dimensional view showing a free iliac bone graft in place to reconstruct fractured orbital floor. | 49 |
| 20 | (A) View of orbital titanium mesh plate 0.4 mm in thickness (Synthes) on a plastic skull model. (B) View of this type of plate being used for reconstruction of a large orbital wall defect. | 54 |
| 21 | Resorbable implant (Synthes Polymax) for orbital wall reconstruction. | 57 |
| 22 | Screen shot of the computed planning of the orbital reconstruction. The red portion represents the area of the injured orbit that differs from the uninjured orbit when the mirroring function of the software is applied; this is the defect area of the orbital floor that needs to be bridged with an implant. | 61 |
| 23 | Finished custom-made orbital floor implant with extension over the infraorbital rim for optimal orientation and fixation | 61 |
| 24 | Schematic on left represents a suboptimal repair of a 2-wall orbit fracture using a single inferior implant with resultant poor orbit contour and implant herniation in the ethmoid sinus. On the right, the same orbit with a “wraparound” implant. Note complete coverage of all fractures and precise re-establishment of normal orbital walls and curvature. | 62 |

| Fig. No. | Title | Page |
|---------------------|---|-------------|
| 25 | Intraoperative findings. (A) Endoscopic findings of inferior orbital wall fracture from through trocar and the orbital fat of the inferior orbital wall (white arrow). (B) Endoscopic findings of a balloon reducing the inferior orbital wall fracture. (C, D) Endoscopic findings of tying using Endoloop and cutting catheter (black arrow). | 64 |

INTRODUCTION

Blunt trauma to the orbital rim is a frequent cause of both orbital fractures and damage to the surrounding facial bones and soft tissues. Many surgical specialties, including ophthalmologists, otolaryngologists, maxillofacial specialists, neurosurgeons, and plastic surgeons, evaluate and treat orbital fractures. A wide range of treating physicians means that varying levels of expertise and experience are involved in the care of patients with periorbital trauma (*Joseph & Glavas, 2011*).

Trauma to the orbital region can result in considerable facial deformity and can affect vision and the nervous system of the face. Rehabilitation of the patient requires an understanding of the alteration in form and function of the orbit, including the intraorbital and intraocular tissues, and the materials and methods available for repair (*Kontio & Lindqvist, 2009*).

The indications for surgery on orbital floor fractures are controversial. Strong indications include enophthalmos greater than 2 mm, significant hypoglobus, or diplopia. Certain consensus also prevails regarding the need for surgery when there is an increase of orbital volume more than 1 cm³. When there are lesser degrees of trauma, disagreement remains regarding the best

method of treatment. The timing of surgery for orbital fractures has also been a controversial issue. Orbital fractures differ from all other facial fractures in that surgery does not typically attempt to achieve bone healing. Rather, the goal of surgery is simply to reconstruct the defect area of the fractured wall. As such, delaying the operation for varying periods of time is feasible. Rarely can it be considered an emergency operation (*Kontio & Lindqvist, 2009*).

The material of choice for wall reconstruction has also been under continued debate. There is general agreement that the ideal material for repairing the orbital floor should be rigid enough to support the orbital contents and should restore the original orbital form and volume. It should be safe and user friendly so that even inexperienced surgeons can handle it. It is the responsibility of the surgeon to recognize the diversity of the materials available and to apply them selectively in clinical use (*Kontio & Lindqvist, 2009*).

AIM OF THE STUDY

The aim of this essay is to review different aspects of management of orbital fractures

ANATOMY OF THE ORBIT

The orbit is essentially intended as a socket for the eyeball and also contains the muscles, nerves and vessels, which are essential for its proper functioning. Moreover, it serves to transmit certain vessels and nerves destined to supply areas of the face around the orbital aperture. Seven bones share in the formation of the orbit which are the maxilla, the palatine bone, the frontal, the sphenoid and zygomatic bone, the ethmoid and the lacrimal bone (*Bron et al., 1997*)(Fig 1).

Fig. (1): Bones sharing in the formation of the orbit.
(www.drthalu.com,2012)

Each orbital cavity is pear-shaped and its apex is directed posteriorly, medially and slightly upward; the stalk of the pear lying within the optic canal. The medial wall runs anteroposteriorly parallel to the sagittal plane while the lateral wall diverges at an angle of about 45 degrees (*Snell & Lemp, 1998*) (Fig 2).

Fig. (2): The orbit (www.drtbalu.com,2012)

The roof or the vault of the orbit is triangular in shape, Formed mainly by the triangular orbital plate of the frontal bone and behind this by the lesser wing of the sphenoid. It does not look

directly downwards but slightly forwards as well (*Bron et al., 1997*).

Anteromedially the roof is invaded by the frontal air sinus. Anterolaterally there is a slight depression, the lacrimal fossa, for the orbital part of the lacrimal gland. Medial to the supraorbital notch and 4 mm behind the orbital margin is a small depression or spine for the pulley of the superior oblique muscle (*Snell & Lemp, 1998*).

Structure: The roof of the orbit is very thin, translucent and fragile except where it is formed by the lesser wing of sphenoid, which is 3 mm thick. If the bone be held up to the light, one can make out the ridges and depressions on the cranial aspect formed by the sulci and gyri of the frontal lobe of the brain. This is especially true for the posterior two thirds. The translucency of the anterior third enables the outline of the orbital extension of the frontal sinus to be seen. Penetrating wounds through the lids are sometimes inflicted with the points of umbrellas or walking-sticks and the roof of the orbit may easily be fractured by direct violence, leading to frontal lobe injury (*Schuenke et al., 2007*).

Relations: The frontal nerve lies in direct contact with the periorbita for the whole extend of the roof where the supraorbital artery accompanies it only in the anterior half. Beneath the nerve

is the levator palpebrae, and deep to this again is the superior rectus. The Trochlear nerve lies medially, in contact with the periorbita. The lacrimal gland adjoins the lacrimal fossa, and the superior oblique lies at the junction of the roof and the medial wall. Invading the roof to a variable extent are the frontal and the ethmoidal sinuses. Above the roof are the meninges covering the frontal lobe of the brain (*Agur & Lee, 1999*).

The Medial wall of the orbit runs parallel with the sagittal plane, and consists from before backwards of four bones united by vertical sutures which are the frontal process of the maxilla, the lacrimal bone, the orbital plate of the ethmoid and a small part of body of sphenoid, where the orbital plate of the ethmoid takes by far the largest portion (*Bron et al., 1997*).

On the anterior part of the medial wall is the lacrimal groove for the lacrimal sac. The lacrimal groove is formed by the lacrimal bone posteriorly and the frontal process of the maxilla anteriorly. The groove is bounded in front and behind by the anterior and posterior lacrimal crests. Below, the lacrimal groove is continuous with the nasolacrimal canal (*Snell & Lemp, 1998*)(Fig 3).
