Acknowledgments

*First and forever, thanks to **Allah**, Almighty for giving me the strength and faith to complete my thesis and for everything else.*

*I wish to express my deepest thanks, gratitude and appreciation to **Prof. Dr. Azza Mohamed Youssef**, Professor of Pediatrics, Faculty of Medicine, Ain Shams University, for her meticulous supervision, kind guidance, valuable instructions and generous help. I really have the honor to complete this work under her supervision.*

*Special thanks are due to **Dr. Wessam Ahmed Ibrahim Ahmed**, Assistant Professor of Pediatrics, Faculty of Medicine, Ain Shams University, for her sincere efforts and fruitful encouragement throughout the whole thesis.*

*I would like also to thank **Dr. Dina Ahmed Soliman**, Assistant Professor of Clinical and Chemical Pathology, Faculty of Medicine, Ain Shams University, for the efforts and time she has devoted to accomplish this work.*

I would like to express my gratitude to all members who assisted me in various ways to establish this work.

 **Mahmoud Naguib Abdelfattah Elshiekh**

ABSTRACT

BACKGROUND: Attention deficit hyperactivity disorder (ADHD) is considered one of the most common neurobehavioral disorders of childhood. In recent years, the impacts of various hormones on ADHD have been studied. However, testosterone has received much less attention. The aim of this study was therefore to investigate serum total testosterone level in children with ADHD.

METHODS: This is a case control study of 70 ADHD patients were recruited from Child and adolescent psychiatry clinic in the children hospital, Ain shams university and 30 healthy controls were included in the study. The mean age of both groups was 7.82 ± 1.4 and 7.52 ± 1.4 years old respectively. Serum total testosterone was measured by Electrochemiluminescence immunoassay.

RESULTS: Serum total testosterone was found to be significantly higher in children with ADHD compared to healthy controls ($P < 0.01$).

CONCLUSION: This study has evidenced a significant high level of serum total testosterone in children with ADHD. There is an association between higher serum total testosterone concentration and ADHD in childhood. Therefore there is a need for regular monitoring of serum total testosterone levels and treatment of patients with high testosterone level.

KEYWORDS: attention-deficit-hyperactivity disorder; children; total testosterone

Introduction

Attention deficit hyperactivity disorder (ADHD) is a debilitating mental health disorder, which is marked by symptoms of inattention, overactivity and impulsiveness that have an early onset, and are age inappropriate, persistent and pervasive. It affects children over their school years and into adulthood and is associated with a number of impairments that impinge on a range of social and health care systems (education, criminal justice, mental health, social services and so on). Those with ADHD are at increased risk of delinquency, criminality, educational failure and mental illness (*McCann et al., 2014*).

ADHD is considered to develop from an interaction between genetic and environmental factors, with numerous developmental neurotoxicants significantly increasing the risk for a diagnosis of ADHD (*Malin and Till, 2015*).

Sex hormones play many roles in the development and function of the human body and brain. Organizational effects of hormones are believed to play an important role in the structural organization of the brain and body with subsequent effects on sex typed behavior (*Roberts and Martel, 2013*).

Testosterone affects the behavior of adults, but little is known about how it might affect the behavior of children. The few available studies of children have focused on aggression, hyperactivity and other behavior disorders (*Mehta et al., 2008*).

Aim of the Work

This study aims at:

- Evaluation of testosterone level in a group of pediatric patient with ADHD and comparison of these levels with a control children.
- Correlation of levels to disease severity.

Attention Deficit Hyperactivity Disorder (ADHD)

Attention Deficit Hyperactivity Disorder (ADHD) is considered one of the most common neurobehavioral disorders of childhood (*Wolraich et al., 2011*). ADHD is characterized by the early onset of age-inappropriate persistent and pervasive symptoms of inattention, hyperactivity and impulsivity (*Banaschewski et al., 2010*).

Clinical presentation is heterogeneous with three subtypes identified according to the most prevalent symptoms (primarily inattentive, primarily hyperactive/ impulsive, and combined) and with a relative context dependence of symptom expression although the condition has a chronic course (*Fair et al., 2012*).

ADHD is associated with cognitive impairments in inhibitory control and executive functions (Fair et al., 2012) but neuropsychological profiles of subjects with ADHD, despite significantly differing from controls in group comparisons, also show considerable inter and intra individual variability. This clinical heterogeneity is likely to reflect the multiplicity of causal pathways leading to the development of the disorder and of a series of moderating and mediating factors involved in symptom expression (*Lahey et al., 2005*).

Diagnosis of ADHD:

There are two sets of diagnostic criteria used to define ADHD: the Diagnostic and Statistical Manual of Mental Disorders, fifth edition (DSMV) (*American Psychiatric Association et al., 2013*) (Previously the DSM-IV-TR which was used before May 2013) and the International Classification of Diseases, tenth edition (ICD-10) (*World Health Organization et al., 1992*).

DSM-V-Diagnostic Criteria for Attention Deficit Hyperactivity Disorder (*American Psychiatric Association, 2013*) must meet criteria for inattention, hyperactivity/impulsivity, or both.

1. Inattention

17 and younger: Six or more of these symptoms must be present for at least 6 months, be inconsistent with the child's developmental level, and have a negative effect on their social and academic activities. To be endorsed, the following must occur "often":

- Often fails to play close attention to details
- Often has trouble sustaining attention
- Often doesn't seem to listen when spoken to directly
- Often fails to follow through on instructions and fails to finish schoolwork or chores
- Often has trouble getting organized
