2012

بِسْمِ اللَّهِ الرَّحْمَنِ الرَّحِيمِ

قَالُوا سُبْحَانَكَ
لَا عِلْمَ لَنَا
إِلَّا مَا عَلَّمْتَنَا
إِنَّكَ أَنْتَ
الْعَلِيمُ الْحَكِيمُ

صدق الله العظيم

سورة البقرة الآية (٢٢)

Acknowledgements

*To **Allah**, goes all my deepest gratitude and thanks for achieving any work in my life.*

*I would like to express my profound gratitude & deepest appreciation to **Prof. Dr. Ashraf ElZoghby Elsaeed**, Professor of General Surgery, Faculty of Medicine, Ain Shams University for his constant advice, valuable instructions & for the time & effort he devoted throughout the entire course of the study.*

*I am deeply thankful to **Prof. Dr. Ahmed Mohamed Nafei**, Assistant Professor of General Surgery, Faculty of Medicine, Ain Shams University, for his willing assistance, enlightening comments & continuous encouragement along the entire course of the study.*

*I wish to extend my gratitude to **Prof. Dr. Samy Gamil Akhnokh** Lecturer of General Surgery, Faculty of Medicine, Ain Shams University for his great support, valuable help and advise through this study.*

Last but not least, my deep appreciation is expressed to all the staff General Surgery of Department Faculty of medicine, Ain Shams University as well as to all members of my family for their cooperation and encouragement.

Introduction

Introduction

The ampulla of Vater, also known as the hepatopancreatic ampulla, is formed by the union of the pancreatic duct and the common bile duct. The ampulla is specifically located at the major duodenal papilla. The ampulla of Vater is an important landmark, halfway along the second part of the duodenum, that marks the anatomical transition from foregut to midgut (and hence the point where the celiac trunk stops supplying the gut and the superior mesenteric artery takes over (*Gan,2007*).

Carcinoma of the ampulla of Vater is a rare malignant tumor arising within 2 cm of the distal end of the common bile duct, where it passes through the wall of the duodenum and ampullary papilla (*Carter, 2008*).

Neoplastic transformation of the intestinal mucosa occurs more commonly near the ampulla than at any other site in the small intestine. Despite this, primary ampullary tumors are rare, with an incidence of approximately four to six cases per million population. They account for only 6 percent of lesions that arise in the periampullary region but are responsible for 20 percent of all tumor-related obstructions of the CBD (*Benhamiche, 2003*).

Ampullary tumors generally present at an earlier stage than periampullary tumors. Their strategic location may cause early biliary obstruction with jaundice (75%), biliary colic, bleeding or pancreatitis. Serum bilirubin and transaminase typically are elevated. Jaundice may intermittently wax and wane because of central necrosis and sloughing or pressure opening of a minimally obstructed duct (*Talamini, 2003*).

Diagnostic imaging modalities for patients with suspected periampullary neoplasms include ultrasonography, computed tomography scanning, magnetic resonance imaging (MRI) and magnetic resonance cholangiopancreatography, endoscopic retrograde cholangiopancreatography, percutaneous transhepatic cholangiography and positron emission tomography. With appropriate use of these studies, one should be able to arrive at the diagnosis of pancreatic cancer in more than 90% of patients presenting with the disease (*Warshaw, 2003*).

Halsted in 1898, was the first who attempted successfully local resection of a periampullary carcinoma, but this patient died 7 months later for a recurrent tumor. Codivilla, was the first to perform en block removal of the entire duodenum with the head of the pancreas for periampullary cancer, and Kausch, performed the first successful such resection using a two-stage approach. A one-

stage pancreaticoduodenectomy was described independently by *Whipple and colleagues (1935) and Brunschwig (1937) (Holzheimer, 2001)*.

Pancreaticoduodenectomy has the benefit of a low recurrence rate, but carries high morbidity (57%) and mortality rates (7%). Conversely, the lower morbidity (19%) and mortality (2%) rates of localized resection of the tumor are associated with higher recurrence rates (23%) (Mean length of hospital stay ranges from 11 to 13 days following localized resection and 15-23 days following pancreaticoduodenectomy *(Cahen, 2002)*).

Since its first description in 1983 by *Suzuki et al* and the first large case series in 1993 by *Binmoeller et al*, endoscopic ampullectomy has gained widespread acceptance for the treatment of benign adenomas. Eradication can be achieved in 85% of cases with low morbidity and mortality. Furthermore, hospitalization can be avoided in most patients, since endoscopic ampullectomy can usually be performed with conscious or deep sedation on an outpatient basis *(Inmoeller, 2004)*.

Aim of the Work

Aim of the work

This study aims at summarizing and critically analyzing the available evidence on the status and future perspective of localized resection of the ampulla of Vater in cases of ampullary carcinoma in comparison to other surgical approaches.
