ACKNOWLEDGEMENT

I would like to express my deepest gratitude and thanks to

Prof. Dr. **Fatma Hassan Abdel-Khalek**

Prof of Obstetrics and Gynaecology, faculty of medicine, Menoufiya University

for her wise guidance and helpful encouragement throughout this work.

I also indebted to

Dr. **Sayed Abdel-Moneium Mahmoud**

Ass. Prof of Obstetrics and Gynecology, Menoufiya University for his

generous offering of valuable supervision.

My great appreciation to

Dr. **Ahmed Nabil Abdel-Hamid Eissa**

Lecturer of Obstetrics and Gynecology, Faculty of Medicine, Menoufiya University.

for his kind helpful support

List of figures

- (1) Normal HSG.
- (2) HSUG, patent left tube.
- (3) HSUG, patent right tube.
- (4) HSG, Bileteral tubal occlusion.
- (5) HSUG, Visualized right tube.
- (6) HSUG, occluded left tube.
- (7) Normal HSG.
- (8) HSUG, right hydrosalpinx.
- (9) HSUG, left patent tube.
- (10) HSG, bilateral cornual block.
- (11) HSUG, right hydrosalpinx.
- (12) HSG, right cornual obstruction and left small hydrosalpinx with no spill.
- (13) HSUG, patent left tube.
- (14) HSG, Peritubal adhesions.
- (15) HSG, Submucous Fibromyoma.

List of tables:

- 1- Demographic criteria of studied women
- 2- Distribution of the studied women according to parity & the type of infertility
- 3- HSG versus laparoscopy
- 4- Patency of each fallopain tube in 24 women. HSG results compared with chromopertubation
- 5- Tubal patency by different contrast media used in HGS.
- 6- HSUG versus laparoscopy
- 7- Patency of each fallopian tube in 24 women.HSUG results compared with chromopertubation.
- 8- HSG versus HSUG (specificity & sensitivity)
- 9- HSG versus HSUG (predictive values)
- 10- HSG versus HSUG (accuracy & disagreement)
- 11- Additional information other than tube patency gained with each maneuver

INTRODUCTION

Introduction

A highly fertile couple practicing coitus regularly without contraception takes an average of six months to achieve pregnancy. Chances of conception are 80% after one year and 90% after one and half year. Failure to conceive after two years is the proper time to start investigations, unless the women is over thirty years and the man is over forty years or as soon as they worry. (Mosher and Pratt, 1993).

Infertility is estimated to occur in ten to fifteen percent of couples, the prevalence has increased in the last decade because of an increase in sexually transmitted diseases resulting in pelvic inflammatory diseases and because of an increasing tendency to delay child bearing. (Krysiewicz, 1992).

The problems of infertility have assumed an increased importance in health care systems in recent years. The advent of new technologies for assisted reproduction has also influenced the overall approach to treatment. (Jones, 1995).

Community awareness of newer reproductive technologies, together with the expectation of couples that they have the inherent right to determine their reproductive destiny, have led to increased demand for fertility-enhancing services. (Jones, 1995).

Considerable progress has been made in understanding of the reproductive physiology and management of infertility including microsurgery and reproductive assisted techniques. (Yoder and Hall, 1991).

Imaging techniques play a significant role in this assessment and with the development and availability of newer and improved techniques of diagnosis which determine the precise underlying cause or causes, thus, the appropriate therapeutic plan could be allowed. (Krysiewicz, 1992).

Of the many different causes of infertility tubal occlusion is one possibility that needs to be excluded or confirmed by investigations. More than one third of infertile patients are attributed to a tubal

factor either as a single or a contributing cause. (Krysiewicz, 1992).

Trans-vaginal sonography has been applied to a wide range of gynaecological disorders particularly in infertility. (Bourne et al, 1993).

Trans-vaginal application enables the effective use of higher frequencies, enhancing resolution with less tissue attenuation. (Mitri et al, 1991).

Sonography of the tubes was frustrated as it is poor sonic reflector, devoid of the defined interfaces that produces a clear organ outline. This creates the need for Hystero-salpingo-ultrasonography (HSUG) using an echo-contrast medium. (Mitri et al, 1991).

AIM OF THE WORK

Aim Of The Work

The aim of the present study is to evaluate the method of transvaginal hystero-salpingo-ultragraphy (HSUG) with the traditional hysterosalpingography (HSG) for estimation of tubal factor as a cause of infertility.

REVIEW OF LITERATURE

TUBAL ANATOMY

The oviduct is the anatomic connection between the ovary and the uterus. As such it is the site of numerous functionally and temporally complex physiologic processes; most of which are incompletely understood if not entirely unsuspected. Despite its pivotal importance in reproduction and the awareness of this organ's structural and functional complexity, clinical interest in the oviduct remains concerned with its patency. (Eddy, 1990).

Embryologically, the oviducts are derived from the paired upper portions of the paramesonephric ducts whose lower portions fuse to form the uterus. As such, the lumen of each tube is confluent proximally with the endometrial cavity and distally with the peritoneal cavity. Because the ovaries, like the female duct system, develop retroperitoneally high in the abdominal cavity, their subsequent descent into the pelvis pulls the oviducts along with them. By sagging into the peritoneal cavity, the oviducts become surrounded by a double fold of peritoneum which gives rise to the mesosalpinx. Between the leaves of the mesosalpinx, varying amounts of connective tissue are deposited. Through this connective tissue, the vascular, nervous, and lymphatic systems pass from their retroperitoneal origins into the tube. (Eddy, 1990).

The oviduct, therefore, consists of an outer serous coat applied to a layer of loose areolar connective tissue. A tubal myosalpinx and an inner epithelial layer, the endosalpinx which lines the tubal lumen. The tube average ten to twelve centimeters in length, however, marked biologic variability in the size of the oviduct exists between individuals. (Krantz, 1994).

On the basis of morphologic characteristics, the tube may be divided into several distinct *segments*:

A. Interstitial Segment :

It passes through the uterine wall and is therefore surrounded by myometrium, the myosalpinx consists of an outer layer of longitudinally arranged smooth muscle bundles, an intermediate circularly arranged layer and an inner longitudinal layer. The endosalpinx, consisting of secretory and ciliated cells, is composed of four or five low folds which create a cruciform or stellate lumen approx-
