تأثير تمرينات المقاومة المتزايدة على ضغط الدم المرتفع /عماد محمد ابراهيم طه / قسم العلاج الطبيعي لاضطرابات الجهاز الدورى التنفسي والمسنين ، كلية العلاج الطبيعي ، جامعة القاهرة ، ٢٠٠٨ ، رسالة ماجستير. / هيئة الإشراف: أ.د/ زينب حلمي. أستاذ ورئيس قسم العلاج الطبيعي لاضطرابات الجهاز الدورى التنفسي و المسنين ، كلية العلاج الطبيعي - جامعة القاهرة. أ.د/ نجوى عيد صبحي. أستاذ امراض الباطنة، كلية الطب – جامعة القاهرة. د. أكرم عبد العزيز. مدرس بقسم العلاج الطبيعي لاضطرابات الجهاز الدورى التنفسي و المسنين ، كلية العلاج الطبيعي - جامعة القاهرة.

### المستخلص

هدف الرسالة هو تقييم تأثير تمرينات المقاومة المتزايدة على ضغط الدم المرتفع. أجري البحث على أربعين سيدة مريضة يعانين من ارتفاع ضغط الدم - تتراوح أعمارهم بين ثلاثين و خمسين عاما ويتراوح معدل كتلة الجسم ما بين ٢٥ – ٣٥ كجم/م<sup>٢</sup>. تم تقسيمهن الى مجموعتين، كل مجموعة تتكون من عشرين مريضة. المجموعة الاولى (أ) تلقت تمرينات المقاومة المتزايدة بالإضافة الى الانتظام على ادوية الضغط المعتادة، بينما التزمت المجموعة الثانية (ب) بأدوية الضغط المعتادة فقط. وقد استمر البرنامج لمدة عشرة اسابيع (بمعدل ثلاث جلسات اسبوعيا). وقد تم قياس و تسجيل مستوى ضغط الدم قبل بدء و بعد البرنامج العلاجي لكلا المجموعتين وقد أظهرت النتائج وجود فروق ذات دلالة إحصائية تشير إلى وجود تحسن ملحوظ في مستوى ضغط الدم لدى المرضى المشاركين فى المجموعة الاولى (أ) ونقص ملحوظ فى جرعات أدوية علاج الضغط، بينما لم تظهر المجموعة (ب) أية فروق ذات دلالة إحصائية فى مستوى ضغط الدم لدى المرضى المشاركين فيها.. لذلك يوصى باستخدام تمرينات المقاومة المتزايدة بالإضافة الى ادوية الضغط المعتادة لخفض مستوى ضغط الدم عند مرضى ضغط الدم المرتفع.

**الكلمات الدالة:** ارتفاع ضغط الدم ، تمرينات المقاومة المتزايدة. السيدات

## *ACKNOWLEDGMENT*

*First and foremost, I would like to kneel thanking for ALLAH, the most beneficial that enabled me to conduct this work, as a part of his generous help throughout life.*

*I am deeply indebted to Prof. Dr. Zeinab Helmy, Professor and chairman of Physical Therapy for Cardiovascular /respiratory disorder and Geriatrics, Faculty of Physical Therapy Cairo University, for her great support and advice that gave me the confidence and encouragement to start and complete this study as the best as I could do.*

*I am profoundly grateful to Prof .Dr. Nagwa Eid Sobhy, professor of Internal medicine, Faculty of Medicine, Cairo University, for her kind help to achieve the clinical section of this work, constant encouragement, constant supervision and advice.*

*Words fail to express my gratitude, respect and appreciation to Dr. Akram Abd El-Aziz, lecturer of Physical Therapy for Cardiovascular/respiratory disorder and Geriatrics, Faculty of Physical Therapy, Cairo University, for his sincere supervision, valuable advice, constructive criticism and continuous support.*

*Finally, I would like to thank my colleagues in the department for their sincere support and kind help especially Dr. Sherein Hasan for her real effort and time that she gave to me. And I cannot forget to thank all patients who participated in this study for their great cooperation during the whole study.*

**Effect of Progressive Resistive Exercise on Systemic Hypertension**  
**Emad Mohamed Ibrahim Taha**, Department of physical Therapy for Cardiovascular/respiratory disorder and Geriatrics, Faculty of Physical Therapy, Cairo University, 2008, Master thesis.

Supervisors: **Prof. Dr. Zeinab helmy. Dr.Akram Abd-Al-Aziz.** In Department of Physical Therapy for Cardiovascular/respiratory disorder and Geriatrics, Faculty of Physical Therapy, Cairo University.  
**Prof. Dr. Nagwa Eid Sobhy** In Department of internal medicine, Faculty of Medicine, Cairo University.

### **Abstract**

The aim of this study was to assess the effect of progressive resistive exercise (PRE) on essential hypertension. Forty Essential Hypertensive female with mild hypertension participated in the study, their age ranged from 30 to 50 years. They were divided into two equal groups. Group (A) performed the PRE program plus taking their ordinary anti-hypertensive medications while group (B) only took their anti-hypertensive medications. The program continued for 10 weeks (three sessions per week). Blood pressure was measured at the beginning of and after the exercise program for both groups. It can be concluded that PRE program for 10 weeks together with antihypertensive drugs produced significant change of the dose of antihypertensive drugs with significant reduction of the systolic blood pressure.

## **List of Abbreviations**

ACE	Angiotensin Converting Enzyme
BP	Blood pressure
BMI	Body Mass Index
CBC	Complete Blood Picture
CV	Cardiovascular
CO	Cardiac Output
DA	Dopamenrgic
DASH	Dietary Approaches to Stop Hypertension
DBP	Diastolic Blood Pressure
EH	Essential Hypertension
HTN	Hypertension
HR	Heart Rat
LVH	Left Ventricular Hypertrophy
MET	Metabolic Equivalent
MVC	Maximum Voluntary Ventilation
PIH	Pregnancy Induced Hypertension
PRE	Progressive resistance exercise
RM	Repetition Maximum
SBP	Systolic Blood Pressure
SNA	Sympathetic Neural Activity

# **Chapter I**

## **Introduction and Aim of the work**

The American Society of Hypertension (ASH) announced an expanded definition of hypertension. The new description extends the definition of hypertension beyond a simple blood pressure (BP) reading to include overall cardiovascular (CV) risk, and incorporates the concept that, in many cases, elevated BP may be the effect and not the cause of hypertension. The new definition incorporates the presence or absence of risk factors, early disease markers and target-organ damage, and more accurately represents the different physiological abnormalities in the CV (cardiovascular) system and other organs caused by hypertension. (**Carman et al., 1994**)

Although exercise programs have traditionally emphasized dynamic lower-extremity exercise, research increasingly suggests that complementary resistance training, when appropriately prescribed and supervised, has favorable effects on muscular strength and endurance, cardiovascular function, metabolism, coronary risk factors, and psychosocial well-being. This advisory reviews the role of resistance training in persons with and without cardiovascular disease,

with specific reference to health and fitness benefits, rationale, the complementary role of stretching, relevant physiological considerations, and safety. Participation criteria and prescriptive guidelines are also provided. (**Michael et al., 2000**).

Systolic blood pressure increases in proportion to the rise in cardiac output, whereas diastolic blood pressure is determined by the balance between vasodilatation and vasoconstriction in the vascular beds (i.e. total peripheral resistance). During dynamic exercise with a large active muscle mass, diastolic blood pressure may decrease at higher exercise intensities. Despite this, the increase in systolic blood pressure results in an elevated mean arterial pressure during incremental exercise. The simultaneous increase in blood pressure and heart rate occurs due to resetting of the baroreflex during exercise (**Norton et al., 1999**).

The principles of progressive resistance exercise (PRE) for increasing force production in muscles have remained virtually unchanged since they were described by DeLorme and Watkins almost 60 years ago. These principles are (1) to perform a small number of repetitions until fatigue, (2) to allow sufficient rest between exercises for recovery,

and (3) to increase the resistance as the ability to generate force increases. These principles are detailed in the guidelines of the American College of Sports Medicine (ACSM), where it is recommended that loads corresponding to an 8- to 12-repetition maximum (RM) be lifted in 1 to 3 sets, training 2 or 3 days each week. An 8RM to 12RM load is the amount of weight that can be lifted through the available range of motion 8 to 12 times before needing a rest. **(DeLorme et. al.; 1948 and American College of Sports Medicine. 2002).**

Meta-analytic review of different studies suggests that dynamic resistance exercise reduces resting systolic and diastolic blood pressure in adults. However, it is premature to form strong conclusions regarding the effects of dynamic resistance exercise on resting blood pressure. A need exists for additional, well-designed studies before a recommendation can be made regarding the efficacy of dynamic resistance exercise as a nonpharmacological therapy for reducing resting blood pressure in adults, especially in hypertensive adults. **(George Kelley, 1997)**

Anti-hypertensive medications has a lot of side effects that require more effort from Physical therapists to establish

a physical program to decrease the dose of these drugs, the side effects ranged between unsteadiness, weight gain, urinary problems, headache, tiredness and sexual problems. **(John Benson and Nicky Britten, 2006).**

### **Statement of the problem**

As the hypertension became one of the most common diseases facing the health professionals, with increasing number of hypertensive subjects, so this study was made as a trial to control hypertension by using the resistive exercise.

### **Purpose of the study**

The purpose of the study is to determine the effect of progressive resistive exercise on reducing the systemic blood pressure or not.

### **Limitation**

The study will be limited according to:-

1. The patient ability to follow the whole program (10 weeks).
2. Difficulty facing the female patients during the resistive exercise program (musculoskeletal injuries).
3. Small sample size.
