

**CARDIOVASCULAR MORBIDITY AMONG YOUTH:
DETERMINANTS AND IMPACT ON HEALTH RELATED
QUALITY OF LIFE**

Thesis Submitted For Fulfillment of M.D. Degree In Public Health By

Salwa Mohamed Hassan Ali

M.Sc.

Under the Supervision of

Dr. Madiha Said Mohamed Abdel Razik

Professor of Public Health
Faculty of Medicine
Cairo University

Dr. Mona Ibrahim El Lawindi

Professor of Public Health
Faculty of Medicine
Cairo University

Dr. Hanan Abdelghani El Raghi

Professor of Public Health
Faculty of Medicine
Cairo University

Dr. Zainab Attia Ashour

Professor of Cardiology
Faculty of Medicine
Cairo University

Faculty of Medicine
Cairo University
2010

Acknowledgement

To begin with, I must thank God for all the blessings bestowed upon me, and the greatest gift of all is an appreciation of these blessings.

*A well known saying is that “motivation gets you through the day, but inspiration lasts a lifetime”. That being said, I consider **Dr. Madiha Said Abdelrazek**, Professor of Public Health, Faculty of Medicine Cairo University, a principle source of inspiration in my life...at work, at home, in Egypt and abroad, professionally, and personally. As my supervisor for over a decade, nothing I can say would do her credit, and I thrived on her energy and encouragement. Thank you.*

*I also owe a great deal of gratitude to **Dr. Mona Ibrahim El Lawindi**, Professor of Public Health, Faculty of Medicine Cairo University. As an academic of expert professional caliber, much of the work on this thesis was based on her guidance and assistance. Through her supervision, I learned the value of research which adheres to strict scientific and ethical standards.*

*My sincere appreciation also goes to **Dr. Hanan Abdelghani El Raghi**, Professor of Public Health, Faculty of Medicine Cairo University, whose generous and valuable advice helped me in times of difficulty that inevitably accompany any major research project.*

*I am especially indebted to **Dr. Zainab Ashour**, Professor of Cardiology, Faculty of Medicine Cairo University. I consider it an honor of the highest degree to have had the opportunity to work under her guidance. She volunteered her time and expertise generously, and enlightened me on much of the clinical aspects and humane plight of the patients, for whom she has a unique passion.*

All due acknowledgement must go to the patients, doctors, nurses, and staff at the National Heart Institute. In addition to their kind cooperation, this institution provided me with access to the incredibly large and diverse pool of patients necessary to complete this work.

Last but not least, major credit for this work, goes to my family, both my nuclear family at home and my extended family in the Department of Public Health.

Abstract

CARDIOVASCULAR MORBIDITY AMONG YOUTH: DETERMINANTS AND IMPACT ON HEALTH RELATED QUALITY OF LIFE

Introduction: cardiovascular diseases (CVD) are among prevalent and preventable of all health problems, resulting in decreased quality of life for millions of people. Unfortunately, developing countries suffer the most, As for Egypt ,CVD, particularly rheumatic heart disease is a significant health problem. Youth represent a priority group. Internationally, there is extensive research assessing the QOL of CVD patients, but there is a lack of such studies among the youth age group. This also applies on a local scale in Egypt.

Objective: of the study include an investigation the epidemiological profile of cardiovascular disease among the studied group of youth, a Quality of life Assessment of the cases compared with the controls, and a study of the possible determinants showing a significant association with QOL. And finally development of an Egyptian HRQL model to predict QOL among cardiovascular diseased youth.

Subject & Methods:

an analytic case control study that involved 500 patients and 500 apparently health controls. Age range 18-24 years , was performed in the cardiology department of the Kasr el Aini Hospital as well as the National Heart Institute. All cases and control were subject to a generic QOL tool (i.e the SF-36v.2) and a disease specific tool (MacNew Heart Disease HRQL questionnaire) was used to study QOL among the rheumatic heart disease group.

Results:

The results of this study can be divided into following sections: background Characteristics of the studied groups: epidemiologic profile of the cases: quality of life(QOL)summary of all study group: determinants of QOL among the cases and qualitative analysis of patient interviews.

Conclusion & Recommendations:

The study results showed that cardiovascular diseases have a negative impact on almost all aspects of the quality of life of diseased youth when compared to their healthy counterparts. Furthermore, RHD scored higher QOL than those with other CVDs. The study recommended establishing comprehensive strategies to improve their quality of life that follow four paths simultaneously : prevention, Treatment, Rehabilitation, and further Research.

Key Words:

Cardiovascular Disease, Rheumatic Heart Disease, Youth, Quality of life (QOL)

INTRODUCTION

By 2050, the number of youth will have risen from just under a half billion in 1950 to 1.2 billion. And the growth of the world's youth population (ages 15 to 24) is shifting into the poorest countries because at that point, about nine in 10 youths will be in developing countries. This generation will need employment, adequate health care, and the ability to raise a family with an appropriate living standard if they so choose. Before those things can come about, they must have had access to sufficient education and training so that they can take part in building their country's society and economy. Improving young people's health and quality of life is a critical goal in and of itself, with long-term benefits to society as a whole (*Population Reference Bureau, 2009*).

While urbanization brings greater access to education and health services, it also carries greater exposure to many risks including chronic non communicable diseases. Today's technological and medical advances have increased the life span of children with severe chronic illnesses and disabilities with more than 90% now reaching the age of 20 (*Whitehouse and Paone, 1998*).

Today, chronic diseases—such as cardiovascular disease (primarily heart disease and stroke), cancer, rheumatic disorders and diabetes—are among the most prevalent, costly, and preventable of all health problems. The prolonged course of illness and disability from such chronic diseases results in extended pain and suffering and decreased quality of life for millions of people (*CDC, 2003*).

Unfortunately, developing and least developed countries suffer the most, where there is more exposure to risk factors, and less access to effective and equitable health care services, such that over 80% of the world's deaths from cardiovascular disease occur in these countries. As for Egypt, it was estimated that 42% of deaths in 2002 were due to cardiovascular diseases making it the first leading cause of death. Early diagnosis

and management can play an important role in management and prevention (*El-Gabaly, 2010*).

Youth with chronic health conditions face two simultaneous transitions: a developmental transition (from childhood to adolescence to adulthood) and a situational institutional transition (from pediatric to general health care). They may also have a third transition, from relative health to illness, depending on the progression of their illness (*Whitehouse and Paone, 1998*).

Physicians have often used health-related quality of life (HRQL) to measure the effects of chronic illness on their patients in order to better understand how an illness interferes with a person's day-to-day life (*CDC, 2003*).

The WHO defines quality of life as "individuals' perceptions of their position in life in the context of the culture and value system in which they live in relation to their goals, standards, and concerns. Quality of life is reflected in the general well being (*WHO, 1993*).

HRQL, the concept of a person or group's perceived physical and mental health over time, expands the statistical toolbox we use to measure individual and community health, to compare communities and regions, and to plan and gauge the impact of our health services and public health programs (*Horton, 2001*).

Quality of life (QOL) surveys, which are one example of outcome research, provides the data for evidence-based medicine. Both activities work together in a continuous quality improvement cycle under the general heading of disease management (*Chatburn, 2001*).

Adolescent health care is challenging not only for general practitioners but for healthcare professionals involved in service delivery at all levels. Youth is a unique stage in the life span of an individual, and so the traditional management regimens
