# Introduction

---

Supraventricular arrhythmias represent a common group of rhythm disturbances including rhythms emanating from the sinus node, atrial tissue (atrial flutter), junctional/reciprocating or accessory pathway-mediated tachycardia.<sup>1</sup>

*AV nodal re-entrant tachycardia (AVNRT)* is the most common type of re-entrant supraventricular tachycardia (SVT). It involves an additional accessory pathway through the AV node that becomes a reentry circuit causing the tachycardia.<sup>2</sup> Although controversy still exists about the exact nature of the tachycardia circuit, abundant evidence has indicated that two pathways in the region of AV node participate, one with relatively fast conduction but long refractoriness and the other with shorter refractoriness but slower conduction. PACs can encounter refractoriness in the fast pathway, conduct down the slow pathway, and reenter the fast pathway retrogradely, initiating the AVNRT. Although this is the most common presentation of AVNRT, some patients have what appears to be propagation in the opposite direction in this circuit (antegrade fast, retrograde slow), as well as "slow-slow" variant. Two or more of these variants can exist in the same patient.

*AV re-entrant tachycardia (AVRT)* actually results from an accessory pathway (AP) of atrioventricular (AV) conduction

that may develop circus movement so as to cause tachycardia. Orthodromic AVRT is the most common form. It occurs as a result of antegrade conduction through the normal AV conduction system and retrograde conduction to the atria via the AP. Less commonly, conduction occurs in the opposite direction resulting in antidromic AVRT.

Therefore, reciprocating atrioventricular tachycardia can be categorized into common slow-fast atrioventricular node re-entrant (AVNRT) and orthodromic atrioventricular reciprocating tachycardia (AVRT).<sup>3</sup>

The electrocardiogram (ECG) during tachycardia is useful in distinguishing these two mechanisms. Several studies examined the diagnosis utility of the ECG, and various algorithms were previously reported.<sup>4,5</sup>

The presence of a pseudo-R'-wave in lead V1 or pseudo-S-wave in the inferior leads has been widely used, although the value of an isolated aVL lead to distinguish both mechanisms has not been thoroughly evaluated yet .

Previous studies have shown that only 80% of narrow QRS supraventricular tachycardia (SVT) types can be differentiated by standard 12-lead electrocardiographic (ECG) criteria.<sup>6</sup>

P waves separate from the QRS complex were observed more frequently in AVRT (70%) and atrial tachycardia (80%).

Pseudo-R' deflection in lead V1, pseudo S wave in inferior leads, and cycle length alternans were more common in AVNRT (55, 20, and 6%, respectively). QRS alternans was also present during AVRT (28%). ST-segment depression ( $\geq 2$  mm) or T-wave inversion, or both, were present more often in AVRT (60%) than in AVNRT (27%). During sinus rhythm, manifest pre-excitation was observed more often in patients with AVRT (42%).<sup>6</sup>

In another study, ST-segment elevation in lead aVR during tachycardia was used to differentiate the narrow QRS complex tachycardia. It appears that aVR ST-segment elevation during narrow QRS complex tachycardia favors the atrioventricular re-entry through an accessory pathway as the mechanism of the tachycardia.<sup>7</sup>

A study that was carried out in 2009 revealed that the aVL notch sensitivity and specificity to determine the final diagnosis was higher than the standard criteria (aVL notch 48.6 and 92.6%; pseudo-S-wave 45 and 91.3%; and pseudo-R'-wave in V1 39.7 and 88.5%, respectively), but it did not reach statistical significance.<sup>3</sup>

Catheter-based slow pathway modification has become a first line treatment of AVNRT with success rates approaching 100 percent.<sup>8</sup>

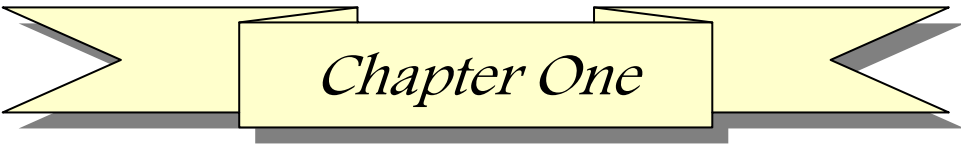

Predicting the mechanism involved in a supraventricular tachycardia before the beginning of the ablation procedure may help in planning the ablation in advance.<sup>3</sup>

---

## **Aim of the work**

---

The purpose of this study is to determine whether an isolated aVL lead of the surface 12-lead ECG is useful for the differential diagnosis between AVNRT and AVRT.

## *Chapter One*

# **Supraventricular tachyarrhythmias**

---

## **I. Background:**

Supraventricular tachycardia (SVT), a common clinical condition, is any tachyarrhythmia that requires only atrial and/or atrioventricular (AV) nodal tissue for its initiation and maintenance. It is usually a narrow-complex tachycardia that has a regular, rapid rhythm; exceptions include atrial fibrillation (AF) and multifocal atrial tachycardia (MAT). Aberrant conduction during SVT results in a wide-complex tachycardia. SVT occurs in persons of all age groups, and treatment can be challenging.<sup>9 10</sup>

Paroxysmal supraventricular tachycardia (PSVT) is episodic, with an abrupt onset and termination. Manifestations of SVT are quite variable; patients may be asymptomatic or they may present with minor palpitations or more severe symptoms.<sup>11</sup>

## **II. Epidemiology:**

Supraventricular arrhythmias are relatively common, often repetitive, occasionally persistent, and rarely life threatening.<sup>12</sup>

The precipitants of supraventricular arrhythmias vary with age, gender, and associated comorbidity.<sup>13</sup>
