2013

Dedication

To my great Family:

M y Parents

My lovely Wife &
Children

My Brother & Sister

Acknowledgement

First, I wish to express my deep thanks, sincere gratitude to ALLAH, who always helps me, care for me and granted me the ability to accomplish this thesis.

I would like to express my deepest gratitude, thanks and gratefulness to Prof. Dr. Omar Hussein Omar, Professor of Radiodiagnosis, Faculty of Medicine, Ain Shams University, for his enthusiastic support, continuous encouragement valuable scientific advices, and great help through out of the accomplishment of this work,

I am very grateful to Prof. Dr. Mounir Sobhy Guirguis, Professor of Radiodiagnosis, Faculty of Medicine, Ain Shams University, for his kind supervision, support, indispensable suggestion, and great help through out of course of my thesis.

My sincere thanks to Dr. Naglaa Shebria, Assistant professor of Radiodiagnosis, Faculty of Medicine, Ain Shams University, for her kind and meticulous supervision, support, help, valuable supervision all through the work,

Words can never express my sincere thanks to Misr Radiology Center, for their help performing this research's cases.

I would like to express my everlasting gratitude to all my dear friends, colleagues and all who offered me any kind of help, encouragement wishing them the best of all.

Yasser Metwally Mostafa Khattab

INTRODUCTION

The salivary glands are; pair of parotid; pair of submandibular and pair of sublingual glands (*Grainger and Allison, 1997*).

Different diseases affect the salivary glands such as; inflammatory diseases, autoimmune diseases and neoplastic diseases (*Cotran et al., 1994*).

Imaging of the main salivary glands and ducts can be performed with conventional sialography, sonography, computed tomography and magnetic resonance imaging (*Jager et al., 2000*).

Because of its excellent delineation of ductal system, conventional sialography currently is still considered the standard modality for assessing ductal abnormalities (*Becket et al., 2000*).

In the recent years, rapid technical development has improved accuracy of non-invasive radiological methods including ultrasonography and magnetic resonance imaging. These methods have been widely replacing conventional invasive examinations in scientific research as well as in clinical practice (*El-Miedany, 2004; Takagi et al., 2005 and Tanaka et al., 2008*).

The introduction of Magnetic resonance sialography protocol by *Lomas et al. (1996)* was the first step towards non-invasive fast easy technique for demonstration of the duct

system. This technique is based on principles of MR hydrography, in which T2-Weighted pulse sequences are used to image static fluid. Consequently, stationary saliva within the salivary gland ducts could be seen to have high signal intensity while solid organs had low signal intensity. In addition flowing blood had little or no measurable signal (*Gadodia et al., 2010*).

MR sialography has several advantages over conventional X-ray sialography. These include the absence of any requirement to cannulate the duct and the lack of ionizing radiation. Because the technique is completely non-invasive, it is likely to enable a more accurate assessment of duct caliber, and duct orifice abnormalities will not be obscured as they are with the conventional method. The examination is not contra-indicated by infection. Because saliva is the contrast medium for the technique, a complete ductal occlusion does not preclude imaging the upstream section of the duct system. Finally, this technique does not rely on any manual skills related to cannulation and has been implemented on a widely available conventional clinical MR system (*Lomas et al., 1996 and Heverhagen et al., 2000*).

MR sialography had been used in the examination of patients with salivary duct diseases including the evaluation of sialolithiasis, duct stenosis and sialadenitis (*Varghese et al., 1999; Kalinowski et al., 2002; Morimoto et al., 2004 and Tanaka et al., 2007*).

AIM OF THE WORK

This study aims to:

Assess the role of Magnetic Resonance Sialography in imaging of salivary gland diseases by using conventional sialography as a gold standard.

SALIVARY GLANDS

Saliva serves multiple and important functions. It plays a key role in taste, chewing, speech, digestion and oral health. Saliva is a solvent for the chemical taste components of the food, a lubricant for all oral mucosal surfaces as well as the food bolus, and a supersaturated reservoir of biominerals, such as calcium, phosphate and fluoride, which continually bathes the teeth, facilitating their mineralization. Saliva also buffers against sudden drop in oral PH that can cause teeth to lose their superficial mineral substance. Saliva contains antimicrobial agents that directly kill pathogens (*Berg et al., 2003; De almeida et al., 2008 and Garcia-Godoy & Hicks, 2008*).

Three major, paired salivary glands produce the majority of saliva: the parotid, the submandibular and the sublingual glands. In addition 600-1,000 minor salivary glands line the oral cavity and oropharynx, contributing a small portion of total salivary production (*Silvers and Som, 1998*).

Embryology:

The major salivary glands develop from the 6th – 8th weeks of gestation as an outpouching of oral ectoderm into the surrounding mesenchyme (*Silvers and Som, 1998*).

The growth of the bud is stimulated by underlying ectomesenchyme. This cord of cells branches several times and
