## **Abstract**

**Objectives:** The primary outcome was to evaluate: the correlation between the ultrasound parameters assessed in the first trimester (Crown- rump length, Fetal heart rate, Uterine artery Doppler assessment and Fetal volume measurement) and silent miscarriage, the correlation between different ultrasound parameters and the correlation between the patient clinical characteristics and early pregnancy loss.

**Methodology:** This was a prospective study that included two hundred pregnant women in the first trimester. Each pregnant women was submitted to three ultrasound scans during the first trimester where (Crown- rump length, Fetal heart rate, Uterine artery Doppler assessment and Fetal volume measurement) were assessed. Complete questionnaire was performed including: obstetric history, and symptoms of the current pregnancy

**Results:**In the first scan 33.3% of fetuses with a CRL below the 5<sup>th</sup> centile for gestational age miscarried compared to 8.1% of those with normal CRL ( $p = 0.008$ ). (Odds Ratio: 5.7, 95% Confidence Interval: 1.7-19.2).In the second scan 15.6% of fetuses with a CRL below the 5<sup>th</sup> centile for gestational age miscarried compared to 3.9% of those with normal CRL ( $p = 0.020$ ). (Odds Ratio: 4.6, 95% Confidence Interval: 1.2-18.3).There was a positive correlation between CRL and fetal volume during the first scan, follow up scan and the final scan ( $r = 0.933, 0.900, 0.547$  respectively). Two factors were associated with significantly higher

frequency of miscarriage; history of previous miscarriages ( $p=0.008$ ) (Odds Ratio: 5.1, 95% confidence interval 1.4-18.7) and threatened miscarriage during the current pregnancy ( $p = 0.003$  (Odds Ratio: 5.3, 95% confidence interval 1.8-15.9).

**Conclusion:** CRL below 5<sup>th</sup> centile for the gestational age in the first trimester was associated with increased risk of first trimester silent miscarriage. There was a positive correlation between CRL and fetal volume measurement in the first trimester. History of previous miscarriage and threatened miscarriage in the current pregnancy were associated with increased risk of silent miscarriage in the ongoing pregnancy.

**Key words:** (Crow- rump length, fetal heart rate, Doppler indices, VOCAL, miscarriage)

## *Acknowledgement*

*Firstly and lastly thanks to Allah the most merciful for his help.*

*I would like to express my deepest gratitude to Prof. Mohamed Momtaz Professor of Obstetrics & Gynecology Faculty of Medicine, Cairo University, for his help in choosing the subject of this thesis. I'm greatly thankful to him for his support, enthusiastic encouragement and sincere appreciation.*

*Also I would like to thank Prof. Mona Abou EL Ghar Professor of Obstetrics & Gynecology Faculty of Medicine, Cairo University, for her sincere supervision and the great efforts that she had offered throughout the period of making and revising this thesis.*

*Also I would like to thank Prof. Sherif Negm assistant Professor of Obstetrics & Gynecology Faculty of Medicine, Cairo University for his sincere advice, and supervision which helped to simplify my task of preparing this work.*

*I'm grateful to all my professors, staff and colleagues of the Obstetrics & Gynecology department Cairo University who helped me throughout this work.*

*Many grateful thanks to my family especially my parents for their continuing care, strong support and patience which guided me throughout my whole life.*

*Finally, I'm grateful to the patients for whom all our efforts are devoted.*

## **INTRODUCTION**

Two dimensional ultrasound is a commonly performed investigation in the first trimester of pregnancy to confirm the pregnancy location, viability and gestational age. Measurement of the embryonic and fetal crown – rump length (CRL) is conventionally performed to confirm the gestational age. Smaller than expected fetal crown – rump length has been associated with subsequent pregnancy loss in studies that involved women with threatened miscarriage. Moreover some chromosomal defects are not only associated with high intrauterine lethality but also associated with fetal growth restriction in the first trimester of pregnancy evidenced by smaller than normal fetal crown-rump length. (*Choong et al, 2003*)

Other ultrasound findings that could be associated with subsequent miscarriage include slower embryonic heart rate and abnormal uterine artery Doppler. Presence of poor obstetric history is reflected in the Doppler velocimetry markers of increased uterine artery resistance during the first trimester of subsequent pregnancy. Recent studies confirm the presence of abnormal uterine artery Doppler finding is association with uteroplacental insufficiency. (*Hichey et al, 2005*)

Three dimensional ultrasound evaluation of the human fetus could be used to monitor the fetal development in the various stages of gestation including the first trimester. It is possible that estimation of the fetal volume using 3D volume measurements could be

superior to 2D ultrasound parameters in predicting the pregnancy outcome and fetal volume data base in the first trimester may be a reference table for diagnosing early pregnancy failure. (*Aviram et al, 2003*)

The diagnosis of miscarriage is made in at least 10-20% of pregnancies in the first trimester. However, in pregnancies where fetal viability is demonstrated, the rate of subsequent miscarriage is decreased to 2-16%. (*Mukri et al, 2008*)

### **The aim of work:**

The primary outcome is to evaluate the correlation between each of the ultrasound parameters that were assessed in the first trimester (crown rump length, fetal heart rate, uterine artery Doppler and fetal volume measurement) and early pregnancy loss (e.g. silent miscarriage). And the correlation between different ultrasound parameter to each other. Our aim also was to evaluate the correlation between the patient clinical characteristics and early pregnancy loss.

## **INTRODUCTION TO ULTRASOUND**

### **History:**

The introduction of sonography to obstetrics by Donald and colleagues in 1958 is now regarded as one of the major milestones of modern medicine (*Dunstand and Nix, 1998*).

The story of the development of ultrasound applications in medicine should probably start with the history of measuring distance under water using sound waves. The term SONAR refers to Sound Navigation and Ranging (*Donald, 1974*).

It became possible to obtain information about the fetus and its environment directly with a non-invasive diagnostic procedure considered safe even when used repeatedly. Initially, acceptance of the technique was slow because it was new and unfamiliar and because the equipment was large and cumbersome to use. With the advent of small, mobile, high-resolution, real-time scanners in the mid to late 1970s, the ease of use together with increased physician awareness of the capabilities of ultrasound accelerated its application to an ever-expanding number of pregnancies. In addition, more recent advances in technology and expertise have enhanced image quality and allowed for considerable insight into fetal physiology (*Johnson et al., 1992*).
