## *Acknowledgment*

First and foremost, my deep gratefulness and indebtedness is to Allah, the Most Gracious and the Most Merciful.

I wish to express my great gratitude to **Prof. Dr. Fatma Salah Eldien Mohammed**, Professor of Diagnostic Radiology, Faculty of Medicine, Ain Shams University for accepting the idea of this work, her kind assistance and efforts, which helped me in accomplishing this essay.

I also extend my thanks and appreciation to **Dr. Ahmed Mohammed Mahmoud Abd Rabou**, Lecturer of Radiology, , Faculty of Medicine, Ain Shams University , for his guidance and great help in supervising this work.

My heart is full of thanks to my husband for his assistance; encouragement, patience and support throughout my work, thank you and God bless you.

### Abstract

In our study demonstrating role of combined qualitative analysis of DWIs and quantitative analysis of ADC values we concluded that approaching contrast enhanced MRI not only in detecting pancreatic neoplasms but also in detection of vascular encasement, tumor necrosis and liver metastasis which are essential information for the clinician that reflects disease prognosis and treatment strategies. However, in view of limitations of the study larger studies are needed to confirm these results. We recommend using DWI in conjunction to conventional imaging as a useful modality that aids in assessment of pancreatic neoplasms. In cases with contraindication to contrast administration DW MR imaging can be used as a reasonable alternative technique to contrast-enhanced imaging

Key word

ADC-MR-DWI- IPMN-

Pancreatic cancer is one of the most lethal human cancers and continues to be a major unsolved health problem at the start of the 21st century (**Li et al.,2004**).

Pancreatic cancer has an unfavourable overall 5-year survival of about 5% and one major reason is latediagnosis. At the time of diagnosis, less than 10% of patients are candidates for the only curative treatment, surgical resection (**Jemal et al 2008**).

Although much effort has been devoted to increase the sensitivity for detecting early stage pancreatic adenocarcinomas with conventional imaging techniques, such as ultrasonography, CT, or MRI, but the sensitivity to detect pancreatic cancer is still insufficient (**Li et al.,2004**).

More recently the use of magnetic resonance imaging (MRI)for detection of pancreatic tumors was demonstrated.In particular, faster sequences reduced motion artifacts substantially facilitated successful characterization of pancreatic lesions(**Hänninen et al., 2002**).

Diffusion-weighted magnetic resonance imaging is a technique that has traditionally been used in neuro-imaging for the detection of acute ischemia and other intracranial disease. However, it is increasingly being used in body applications. It is well known that

diffusion is caused by random translational molecular motion, also known as brownian water motion. DWI is the only imaging method that can be used to evaluate the diffusion process in vivo. The speed with which water molecules diffuse differs in extracellular and intracellular components of tissues. In the intracellular component, diffusion is relatively slow because of the presence of cellular membranes(**Ichikawa et al., 2007**).

Thus, ADCs, which are quantitative expressions of the diffusion characteristics of tissues, are related to the proportion of extracellular and intracellular components. ADC values tend to decrease with increased tissue cellularity or cell density. On the other hand, the cell density may be indicative of tumor aggressiveness; the results of several clinical studies suggest an increased metastatic capacity of tumors with high cellularity(**Ichikawa et al., 2007**).

DW MRI is being increasingly utilized in abdominal imaging to qualitatively and quantitatively assess tissue cellularity and cell membrane integrity. In the pancreas, DWI appears to be a promising adjunct for net diagnosis (**Christine Schmid et al.,2013** ).

DW MRI represents a valuable adjunct to T2w images and is comparable to CE T1w images in pancreatic NET detection. DW MRI also allows quantitative differentiation of NET from normal pancreatic tissue with ADC values **(Brenner R. et al., 2012)**.

The ADC value ( $\times 10^{-3} \text{ mm}^2/\text{s}$ ) in the carcinoma was  $1.44 \pm 0.20$ , which was significantly lower compared to that of normal pancreas ( $1.90 \pm 0.06$ ) and tumor-associated chronic pancreatitis ( $2.31 \pm 0.18$ ) **(Matsukiet al., 2007)**.

Also in favor DWI can be easily performed as an adjunct to a conventional MRI study. Furthermore, DW images can be fused with conventional MR images, like the fusion images obtained with PET/CT scanners, to achieve better anatomic resolution. **(Hosten N et al., lancet 2000)**.

## Introduction

---

### **Aim of the work**

---

To illustrate the usefulness of Diffusion weighted MRI in differentiating benign from malignant pancreatic lesions.

### Gross anatomy of the pancreas

The pancreas is compound gland {both exocrine and endocrine} located in the upper part of the abdomen where it lies within the anterior pararenal compartment of retroperitoneum **(Barbi et al., 2012)**.

On average the pancreas measures 15-20 cm in length, is about 3 cm wide, and has a thickness of about 1-1.5 cm in adult **(Moo et al., 2009)**.

There is a gradual decrease in the size of the pancreas with age. Its anteroposterior dimensions in persons 5-60 years of age are as follows: 24 mm (+- 3.6 mm) for the head, 16 mm (+- 2.0 mm) for the body, and 15.1 mm (+- 1.9 mm) for the tail **(Mortele' et al., 2006)**.

### Embryology:

Ventral (caudal) and dorsal (cranial) outpouchings develop at the junction of the foregut and midgut during the fourth week of gestation **(Figure 1.1)**. The dorsal diverticulum forms the dorsal portion of the pancreas, and the ventral diverticulum forms the liver, gallbladder, bile ducts, and ventral pancreas. As the foregut elongates, the

## Anatomy of the pancreas

---

developing ventral pancreas, gallbladder, and bile duct rotate clockwise posterior to the duodenum and join the dorsal pancreas in the retroperitoneum. The ventral pancreatic duct and the common bile duct (CBD) are linked by their embryonic origins, which results in the adult configuration of their common entrance into the duodenum at the major papilla **(Mortele' et al., 2006)**.

**Fig.1.1.** Drawings illustrate Development of dorsal and ventral pancreatic buds at 4<sup>th</sup> week **(Moo et al., 2009)**.

At approximately the 7th gestational week, the dorsal and ventral pancreatic ducts fuse in the region of the neck **(Figure 1.2)**. The territory drained by each system can vary, but in general the dorsal pancreatic ductal system dra

## Anatomy of the pancreas

---

ins the tail, body, and anterior portion of the pancreatic head, whereas the ventral component drains the posterior aspect of the pancreatic head. Both dorsal and ventral ducts variably drain the uncinate process of the pancreatic head **(Mortele' et al., 2006)**.

The portion of the dorsal duct proximal to the dorsal-ventral fusion point is called the main pancreatic duct (MPD); if a segment of the dorsal duct persists distal to the dorsal-ventral fusion point, it is termed the duct of Santorini, or accessory duct. In 30% of individuals, however, the duct of Santorini loses its communication with the minor duodenal papilla and persists only as a branch of the MPD **(Mortele' et al., 2006)**.

## Anatomy of the pancreas

---

**Fig.1.2. Graphic illustrate** the normal embryologic development of the pancreas and biliary tree. The ventral pancreatic bud (arrow in **a** and **b**) and biliary system arise from the hepatic diverticulum, and the dorsal pancreatic bud (arrowhead in **a** and **b**) arises from the dorsal mesogastrium. After clockwise rotation of the ventral bud around the caudal part of the foregut, there is fusion of the dorsal pancreas (located anterior) and ventral pancreas (located posterior). Finally, the ventral and dorsal pancreatic ducts fuse, and the pancreas is predominantly drained through the ventral duct, which joins the common bile duct (CBD) at the level of the major papilla. The dorsal duct empties at the level of the minor papilla (**Mortele´ et al., 2006**).

### Site:

It lies within the anterior pararenal compartment of retroperitoneum (**Figure 1.3**) centrally it lies on the front side of the first two lumbar vertebrae and may also the last dorsal vertebra, with the interposition of abdominal aorta on the left and inferior vena cava on the right, on the right it is surrounded by the duodenal C-loop, on the l
