Acknowledgement

*First, thanks are all due to **Allah** for Blessing this work until it has reached its end, as a part of his generous help throughout our life.*

*My profound thanks and deep appreciation to **Dr. Gamal Eldin Mohammad Ahmad Elewa**, Professor of Anesthesiology, Intensive Care and Pain Management, Faculty of Medicine, Ain Shams University, for his great support, advice, and remarks that gave me the confidence and encouragement to fulfill this work.*

*I am deeply grateful to **Dr. Hanaa Mohammad Abdallah El-Gendy**, Associate Professor of Anesthesiology, Intensive Care and Pain Management, Faculty of Medicine, Ain Shams University, for adding a lot to this work by her experience and for her keen supervision.*

*I am also thankful to **Dr. Eman Mohammad Kamal Abo-Sief**, Lecturer of Anesthesiology, Intensive Care and Pain Management, Faculty of Medicine, Ain Shams University, for her supervision, co-operation and direction that extended throughout this work.*

I am extremely sincere to my family who stood beside me throughout this work giving me their support.

Samar Mostafa

Nutritional Support in Polytrauma Patients with Organ Dysfunction

Abstract

A significant number of deaths in polytrauma occurs days to weeks after the primary insult, caused by infection and organ failure and their resultant hypercatabolic state, causing acute protein malnutrition. Nutrition therapy should be planned and integrated with other measures of management for patients with polytrauma and major burns. The goals of nutrition therapy in these patients include early delivery of nutritional components (energy, protein, fluid and micronutrients), by enteral, parenteral or both routes, to prevent protein energy wasting (PEW), preserve lean body mass (LBM), to promote wound healing. However, resuscitation efforts should precede nutritional support. Critically ill polytrauma patients with their proinflammatory states and increased oxygen free radicals production will benefit from immunonutrition. Immunonutrients include glutamine, arginine, ω -3 fatty acids, Selenium and some vitamins. They are substrates which modulate inflammatory process in order to decrease critical illness severity and avoid complications.

Key words: Polytrauma, critically ill patients, systemic inflammatory response syndrome (SIRS), multiorgan failure (MOF), enteral nutrition (EN), parenteral nutrition (PN), immunonutrition, protein energy wasting (PEW).

Introduction

A significant number of deaths in polytrauma occurs days to weeks after the primary insult, caused by infection and organ failure and their resultant hypercatabolic state, causing acute protein malnutrition. Nutrition therapy should be planned and integrated with other measures of management for patients with polytrauma and major burns. After the initial measures dictated by advanced trauma life support (ATLS), including the airway (A), breathing (B), circulation (C), disability (D) and exposure (E), the letter (F) for feed should be included to reflect the significance of early nutrition support in trauma. There is proportionate relation between nutritional status and the outcome of surgical intervention. Nutritional deficits are associated with increased risk of morbidity and mortality (**Bicudo-Salomao et al, 2013**).

The catabolic state in polytrauma patients must be early recognized and properly managed by appropriate nutritional support. So, there is a great significance of nutrition in these critically ill intensive care unit (ICU) patients (**Hasenboehler et al, 2006**).

Over the past few decades, the studying of the molecular and biological influences of nutrients in

Nutritional Support in Polytrauma Patients with Organ Dysfunction

maintaining homeostasis in the critically ill patients has made great achievements. Conventionally, nutritional support in critically ill patients was considered adjunctive measure designed to deliver exogenous fuels to meet the patient's demands during the periods of stress response (**McClave et al, 2009**).

Nutrition therapy enriched with immunomodulatory substrates aim to improve the hyperinflammatory phase, called systemic inflammatory response syndrome (SIRS) to avoid sepsis and multiorgan failure (MOF) (**Bastian and Weimann, 2002**).

The choice of nutritional care plan should to be altered according to the organ dysfunction to avoid complications as in cases of head injuries, respiratory failure, renal impairment or hepatic impairment (**MaClave et al, 2009**).

Aim of the Essay

The aim of essay was to highlight and discuss the nutritional derangement in polytrauma patients and to identify the suitable nutritional support for such polytrauma patients associated with organ dysfunction.
