# Acknowledgment

**F**irst and foremost, I thank **ALLAH** for helping and guiding me in accomplishing this work.

I would like to express my sincere gratitude to the great **Prof. Dr. Ahmed Nassar**, Professor of Cardiology, Ain Shams University, firstly for giving me the honor to be his student and for his great support and stimulating views. His active, persistent guidance and overwhelming kindness have been of great help throughout this work.

I must extend my warmest gratitude to **Dr. Bassem Wadee**, assistant professor of Cardiology, Ain Shams University, for his great help and faithful advice. His continuous encouragement was of great value and support to me.

Many great thanks for **Dr. Wael Mahmoud El-Kilany**, lecturer of cardiology, Ain Shams University, who has been the real brother and whom fruitful thinking was behind the progress of this work

Last but definitely not the least, I would like to thank my family and my wife for always being there for me and for all the suffering and hardships I made them face from the day I entered this world. To them I owe my life.

<b>VWF</b>	Von Willebrand factor.

# INTRODUCTION

Acute myocardial infarction is one of the most important causes of acute emergencies all over the whole world (*Iqbal MJ et al., 2008*).

Myocardial infarction is either *non-ST segment elevation myocardial infarction* (NSTEMI) or *ST segment elevation myocardial infarction* (STEMI) (*Grech ED et al., 2003*).

Most cases of STEMI are caused by occlusion of a major coronary artery and it represents about 30% - 40% of patients with ACS. Coronary occlusion and reduction in coronary blood flow are usually due to physical disruption of an atherosclerotic plaque with subsequent formation of an occluding thrombus. Concomitant coronary vasoconstriction and microembolization may be involved to some extent (*Fuster V et al., 2005*).

Primary percutaneous intervention (PCI) was found to be the treatment of choice for acute ST elevation myocardial infarction and according to the American College of Cardiology/American Heart Association (ACC/AHA) guidelines,

STEMI patients presenting to a hospital with PCI capability should be treated with primary PCI within 90 minutes of first medical contact(*Qarawani D et al., 2008*).

Staged PCI is the recommended strategy for patients with multivessel disease and stable hemodynamics according to the ACC/AHA guidelines, however some other studies found that multivessel PCI during acute myocardial infarction is feasible and safe and that complete revascularization resulted in limiting the infarct size and improving the acute clinical course (*Khattab AA et al., 2008*) (*Qarawani D et al., 2008*).

Our study aimed at detecting the safety of the complete revascularization strategy in patients with STEMI and multivessel disease provided that the non-culprit lesions are simple lesions which according to the ACC/AHA criteria of coronary artery lesions are considered of high periprocedural success rate and low complication rate(*Kini AS, 2007*).

# AIM OF THE WORK

To compare the in-hospital and short term (6 month) outcome of Staged PCI strategy (i.e. culprit lesion only PCI during the primary PCI followed by PCI to other significant lesions in a later session) versus multivessel PCI strategy in the setting of primary intervention in patients presenting with acute ST segment elevation myocardial infarction and multivessel disease (with non culprit lesions of type A or B only) with no hemodynamic compromise.

## **Acute ST-segment Elevation Myocardial Infarction – Definition and Pathogenesis**

Acute **myocardial infarction** (AMI or MI), commonly known as a **heart attack**, is a disease state that occurs when the blood supply to a part of the heart is interrupted. The resulting ischemia or oxygen shortage causes damage and potential death of heart tissue. It is a medical emergency, and the leading cause of death for both men and women all over the world (*Luepker et al., 2003*).

### **Definition of Myocardial Infarction:**

Recent "Universal Definition of Myocardial Infarction" put by the recent 2012 ESC guidelines (*Thygesen K et al., 2012*) as :-

- Detection of rise and/or fall of cardiac biomarkers (preferably troponin) with at least one value above the 99th percentile of the upper reference limit (URL) together with evidence of myocardial ischemia with at least one of the following:

- 1- Symptoms of ischemia;
  - 2- ECG changes indicative of new ischemia (new ST-T changes or new left bundle branch block [LBBB]);
  - 3- Development of pathological Q waves in the ECG;
  - 4- Imaging evidence of new loss of viable myocardium or new regional wall motion abnormality.
  - 5- Identification of intracoronary thrombus by angiography or autopsy.
- Sudden, unexpected cardiac death, involving cardiac arrest, often with symptoms suggestive of myocardial ischemia, and accompanied by presumably new ST elevation, or new LBBB, but death occurring before blood samples could be obtained, or at a time before the appearance of cardiac biomarkers in the blood.

**Risk Factors:**

**1- Non-modifiable risk factors:**

- Older age
- Male gender (*Wilson et al., 1998*)
