

# **Verification of Analytical Performance of LH750 and HmX Hematology Analyzers**

*Thesis*

**Submitted for Partial Fulfillment of Master Degree  
in Clinical Pathology**

*By*

**Mona Mohamed Mahmoud**  
(M.B.B. Ch., Ain Shams University, 2008)

*Supervised by*

**Professor/ Manal Hashem Ahmed Fayek**

*Professor of Clinical Pathology  
Faculty of Medicine- Ain Shams University*

**Doctor/ Shaimaa Abdelmalik Pessar**

*Lecturer of Clinical Pathology  
Faculty of Medicine- Ain Shams University*

**Faculty of Medicine  
Ain Shams University  
2015**

*First of all, I wish to express my sincere thanks to **ALLAH** for his care and generosity throughout my whole life.*

*I would like to express my sincere appreciation and my deep gratitude to **Prof. Manal Hashem Ahmed Fayek**, Professor of Clinical Pathology, Faculty of Medicine, Ain Shams University who assigned the work, kindly supplied me with all necessary facilities for its success and helped me to complete this work.*

*I am deeply grateful to **Dr. Shaimaa Abdelmalik Pessar**, Lecturer of Clinical Pathology, Faculty of Medicine, Ain Shams University, for her continuous help, support and direct supervision of the work and for her fruitful thinking which was behind the progress of the work.*

*I would like to thank my beloved parents, brothers and sister for their support, love and faith in me throughout my life. My warmest appreciation goes to my husband and my precious kids for their continuous encouragement, sacrifices and for being there for me.*

**Mona Mohamed**

## INTRODUCTION

Human blood cell analysis dates back 330 years to Leeuwenhoek, when he provided the first description of red blood cells using his simple microscope consisting of a minute biconvex lens. Wallace Coulter developed the first automated analyzer for counting and sizing cells and presented it in 1956 (**Chapman, 2000**).

The first hematology analyzers were based on the principle of impedance (resistance to current flow). The analyzer prepares one lysed sample to measure white blood cells (WBCs) and hemoglobin (Hb) values and unlysed sample for the red blood cells (RBCs), hematocrit (Hct), mean corpuscular volume (MCV) and platelet count (**Zandecki et al., 2007**).

The automated counting of RBC have been based on electrical impedance or later on light scattering technique, the hemoglobin is measured optically. The MCV is measured by the electronic cell counter while Hct, MCH and MCHC are calculated (**Chapman, 2000**).

The platelet count is often measured by impedance, both RBCs and platelets are discriminated by their volume and volume histogram is generated later. Flags are triggered for cases corresponding to inability to

differentiate platelets from RBCs. Manual evaluation is required if platelet count is very low, clumping was observed or large platelets were present (**Zandecki et al., 2007**).

The automated differential leukocyte count is a more complicated process; at first the analyzer used volume to provide three part differential analysis of neutrophils, lymphocytes and monocyte. By the use of this reliable inexpensive method the identification of monocytes, immature myeloid cells and nucleated RBCs is difficult and peripheral smear review is necessary (**Gopal et al., 2005**).

Current hematology instruments combine laser technology, impedance, radiofrequency, direct current, optimized temperature and volume to maximize the sensitivity and specificity of WBCs (**Kanzowaska and Bystryk, 2011**). The newer instruments provide five WBCs parameters in relative and absolute count but don't report the band numbers which is detected by manual review (**Senzel et al., 2010**).

The fully automated Coulter instruments Coulter HmX and LH750 produce a five-part differential white cell count, which is based on various physical characteristics of white cells, following partial stripping of cytoplasm. Three

simultaneous measurements are made on each cell; impedance measurements, conductivity measurements and forward light scattering (**Bain, 2006**).

With the latest Beckman–Coulter instrument, the LH750, precision is improved by counting white cells, red cells and platelets in triplicate and by extending the counting time if the WBC or platelet count is low. The instrument is able to count NRBCs and corrects the WBCs for NRBCs interference (**Bain, 2006**).

The advent of automation in the diagnostic laboratory and increasing dependence on machine generated results for analytical tests highlight the importance of laboratory quality management programmes (**Hoffbrand et al., 2009**).

Quality control (QC) can be separated into 2 major categories: internal QC and external QC. Most of the quality control activities take place internally to evaluate the data, and takes rapid corrective action. However, the external QC results are useful as an objective test of the internal QC procedures and may identify errors (i.e., biased or contaminated standards. The validation of automated hematology analyzer results by manual slide review (MSR) is currently an inevitable work process in clinical hematology laboratories (**Hur et al., 2011**).

ISO 15189:2012 specifies requirements for quality and competence in medical laboratories. It can be used by medical laboratories in developing their quality management systems and assessing their own competence and also for confirming or recognizing the competence of medical laboratories by laboratory customers, regulating authorities and accreditation bodies. Verification of automated cell counter specification is a requirement of ISO 15189: 2012 (**ISO15189, 2012**).

## **AIM OF THE WORK**

To verify the analytical performance of LH750 and HmX hematology analyzers as regards the complete blood picture parameters as a preparatory step for laboratory accreditation according to the ISO standard ISO 15189: 2012.

## **AUTOMATED CELL COUNT**

The most commonly performed test in a clinical hematology laboratory is a complete blood count, generally referred to as CBC. The second most commonly performed hematologic test is what is traditionally called differential leukocyte count (DLC) (**Carr, 2012**).

During the first half of the 20<sup>th</sup> century, the complete blood count (CBC) was performed using exclusively manual techniques: (**George, 2014**).

- Blood cell counts (red cells, white cells, platelets) were performed using appropriately diluted blood samples and a hemocytometer.
- Hemoglobin concentration was analyzed by the cyanomethemoglobin method.
- The hematocrit (Hct), was measured by high speed centrifugation of a column of blood, either in the Wintrobe tube or in sealed microcapillary tubes.
- The white blood cell differential was obtained by examining a suitably stained blood smear (**George, 2014**).

In 1932, Wintrobe developed a set of calculated indices that estimated erythrocyte size and hemoglobin
