2010***

ABSTRACT

The incision for the insertion of the expanders were placed 1cm from the margin of the scar on the scar side in stable tissue that is expected to heal, The level of dissection was always subcutaneous and over the deep fascia of the underlying muscles. Suction drains and prophylactic antibiotics were routinely used.

LIST OF Photos

<i>Photo 1-i</i>	Case (1)	Pre-operative: Showing a post-burn scar in the anterior aspect of the thigh in a 26 y old	87
<i>Photo 1-ii</i>		After Expander insertion: through the edge of the scar, the 400 cc expander was intra-operatively.	87
<i>Photo 1-iii</i>		After Full Expansion: 400cc in about 3 months.	87
<i>Photo 1-iv</i>		Showing the dimensions of the scar (13x6cm) and that of the expanded skin (22x26 cm).	87
<i>Photo 1-v</i>		Intra-operatively: showing excision of the scar and coverage by the skin flap.	88
<i>Photo 1-vi</i>		Immediately Post-operative: showing closure without tension	88
<i>Photo 1-vii</i>		Two weeks Post-operative: showing healing of the wound with small widening in the upper medial aspect of the wound.	88
<i>Photo 1-viii</i>		Three weeks Post-operative: showing good healing of the wound.	88
<i>Photo 2-i</i>	Case (2)	Pre-operative: Showing a post-traumatic depressed scar in the left Gluteal region a 12y old female.	89
<i>Photo 2-ii</i>		Insertion of a 250 cc rectangular expander through the edge of the scar.	89
<i>Photo 2-iii</i>		After Full Expansion with 300cc saline in 10 weeks.	89
<i>Photo 2-iv</i>		Immediately before expander removal: showing small ulceration.	89
<i>Photo 2-v</i>		Immediately Post-operative: showing complete excision of the scar and closure of the wound without tension	90
<i>Photo 2-vi</i>		One week post-operative: showing good healing of the wound.	90
<i>Photo 2-vii</i>		One month post-operative: showing widening in the anterior part of the wound	90
<i>Photo 3-i</i>	Case (3)	Pre-operative: Showing a post-traumatic contracture scar in the left posterior thigh in a 43y old female.	91
<i>Photo 3-ii</i>		After insertion of a 500cc circular expander with external valve.	91
<i>Photo 3-iii</i>		After Full Expansion with 500cc in 14 weeks.	91
<i>Photo 3-iv</i>		Showing erythema and ulceration over the expander.	91
<i>Photo 3-v</i>		Immediately Post-operative: showing complete excision of the scar .	92
<i>Photo 3-vi</i>		One week Post-operative: showing good healing of the wound.	92
<i>Photo 4-i</i>	Case (4)	Showing a post-traumatic scar in the lateral aspect of left leg in a 30y old female with a 100cc expander inserted through the edge of the scar	93
<i>Photo 4-ii</i>		Post-operative: showing complete excision of the scar.	93
<i>Photo 5-i</i>	Case (5)	Pre-operative (Lateral view)	94
<i>Photo 5-ii</i>		Pre-operative (Anterior view).	94
<i>Photo 5-iii</i>		After insertion of the Two Expanders (Lateral view) :	94

<i>Photo 5-iv</i>	Case (5)	After insertion of the two expanders (Anterior view).	94
<i>Photo 5-v</i>		Full expansion of the upper expander (Lateral view) with 700cc in 16 weeks.	95
<i>Photo 5-vi</i>		Full expansion of the upper expander (Anterior view).	95
<i>Photo 5-vii</i>		One week post-operative: sowing excision of about 1/3 of the scar.	95
<i>Photo 5-viii</i>		Three weeks post-operative: showing good healing.	95
<i>Photo 6-i</i>	Case (6)	Pre-operative (Lateral view)	96
<i>Photo 6-ii</i>		Pre-operative (Posterior view).	96
<i>Photo 6-iii</i>		Intra-operative: dissection of the pockets with blunt dissector.	96
<i>Photo 6-iv</i>		Intra-operative: using Endoscopic Technique in dissection and homeostasis	96
<i>Photo 6-v</i>		After insertion of two expanders	96
<i>Photo 6-vi</i>		Extrusion of the upper expander after 6 weeks of inflation (lateral view).	97
<i>Photo 6-vii</i>		Extrusion of the upper expander (Anterior view).	97
<i>Photo 6-viii</i>		One month post-operative	97
<i>Photo 6-ix</i>		The closure of the site of extrusion	97
<i>Photo 7-i</i>	Case (7)	Showing a post-traumatic scar in the medial aspect of left thigh in a 27y old female with a 300cc expander inserted through the edge of the scar.	98
<i>Photo 7-ii</i>		Post-operative	98
<i>Photo 8-i</i>	Case (8)	Post-burn Scar on the dorsal aspect of left forearm in a 25y old male with two expanders 120cc each (dorsal view)	99
<i>Photo 8-ii</i>		After Post-burn Scar on the dorsal aspect of left forearm in a 25y old male with two expanders 120cc each (medial view)	99
<i>Photo 8-iii</i>		Post-operative (palmar view)	99
<i>Photo 8-iv</i>		Post-operative (dorsal view)	99
<i>Photo 9-i</i>	Case (9)	Post-burn scar on the medial aspect of the Lt. Arm (early stage)in a 26y old female.	100
<i>Photo 9-ii</i>		Late Stage of the post-burn scar (2 months later) showing decrease in the size of the scar	100
<i>Photo 9-iii</i>		Intra-operative acute tissue expansion (ATE) using a 300cc rectangular expander.	100
<i>Photo 9-iv</i>		Immediately post-operative showing complete excision of the scar without tension.	100
<i>Photo 9-v</i>		One month post-operative: showing good healing of the wound	100
<i>Photo 10-i</i>	Case (10)	Xanthelasma on the left elbow of a 24 old female.	101
<i>Photo 10-ii</i>		Close up view of the lesion	101
<i>Photo 10-iii</i>		After Full expansion of two 150cc expanders above and below the lesion in 10 weeks.	101
<i>Photo 10-iv</i>		The excised lesion.	101

<i>Photo 10-v</i>	Case (10)	Immediately post-operative: showing complete excision of the lesion without tension.	102
<i>Photo 10-vi</i>		Two weeks post-operative: showing good healing of the wound.	102
<i>Photo 10-vii</i>		Six weeks post-operative showing widening of the wound.	102
<i>Photo 11-i</i>	Case (11)	Pre-operative: showing a hairy nevus on the dorsal aspect of the right arm of 23y old female.	103
<i>Photo 11-ii</i>		Full expansion of a 250cc circular expander in 12 weeks	103
<i>Photo 11-iii</i>		Intra-operative after expander removal	103
<i>Photo 11-iv</i>		Post-operative: showing the use of a small split thickness graft to complete the coverage.	103
<i>Photo 12-i</i>	Case (12)	Pre-operative: showing a post-burn scar on the medial aspect of the left arm of 26y old male.	104
<i>Photo 12-ii</i>		Full expansion of a 350cc rectangular expander	104
<i>Photo 12-iii</i>		Immediately post-operative: showing complete excision of the scar and 1ry closure with no tension.	104
<i>Photo 12-iv</i>		3 weeks post-operative: showing hypertrophic scar.	104
<i>Photo 13-i</i>	Case (13)	Post-burn scar on the medial aspect of the Left Arm in an 18y old female.	105
<i>Photo 13-ii</i>		Full expansion of two expanders 300cc above the scar and 250cc below the scar	105
<i>Photo 13-iii</i>		Immediately Post operative: showing excision of the whole scar.	105
<i>Photo 13-iv</i>		Two weeks post-operative: showing good healing of the wound.	105
<i>Photo 13-v</i>		Five months post-operative: showing good healing without widening of the wound.	105
<i>Photo 14-i</i>	Case (14)	Huge hairy Mole in the lateral aspect of left arm in a 37y old female.	106
<i>Photo 14-ii</i>		Full expansion of a 450cc circular expander (Posterior view) in 14 weeks.	106
<i>Photo 14-iii</i>		Full expansion (Anterior View).	106
<i>Photo 14-iv</i>		After expander removal showing reduction in the size of the mole.	106
<i>Photo 15-i</i>	Case (15)	Post-burn Scar in the anterior aspect of the right arm and forearm of a 24y old female.	107
<i>Photo 15-ii</i>		Full expansion of a 400cc rectangular expander.	107
<i>Photo 15-iii</i>		The excised Skin about 10x6 cm	107
<i>Photo 15-iv</i>		Immediately post-operative: showing closure without tension.	107
<i>Photo 15-v</i>		Three weeks post-operative: showing good healing of the wound.	107
<i>Photo 16-i</i>	Case (16)	Post-burn Scar in the medial aspect of the left arm of a 27y old female	108
<i>Photo 16-ii</i>		Medial view of the scar	108
<i>Photo 16-iii</i>		Full expansion of two expanders 150cc above and 200cc below	108
<i>Photo 16-iv</i>		Post-operative showing complete excision of the scar.	108
<i>Photo 16-v</i>		Post-operative (Dorso-medial view).	108

Acknowledgment

Praise to **God** who allowed and facilitated the execution of this work

I wish to express my appreciation to **Prof. Dr. Raafat Gohar**, Professor of Plastic Surgery, Faculty of Medicine, Cairo University, for his continuous supervision, support and for supplying me with everything for this work that made the work achievable.

My Greatest gratitude & thanks for **Prof. Dr. Mostafa Abo El-Soud**, Professor of Plastic Surgery, Faculty of Medicine, Cairo University, for his Great support and Kind and careful assistance and valuable knowledge during this work and all through my residency.

Many thanks to **Prof. Dr. Wael Abd El-Nasser**, Assistant Professor of Plastic Surgery, Faculty of Medicine, Cairo University, for his precious advices , kind supervision and patience during the preparation of this work.

I wish to thank all my professors, my seniors, my colleagues and my family for helping me directly and indirectly to carry on this research.

Aim of Work

The aim of this study is to evaluate and to refine the use of Tissue Expanders in Both upper and lower limbs and to detect the best types and sites of skin incisions and plane insertion for the expander and the number of expanders can be used for each case and to detect the Complication rates and to Evaluate the Cosmetic as well as the Functional benefits for each case.

Historical Perspective:

Tissue expansion is the response of living tissue to the application of a mechanical stretching force (*Radovan, 1984*).

The ability of human tissue to expand and stretch has been observed and documented through history. Dr. William Grapp wrote in 1982, "Heaven only knows that the principle of skin expansion has been staring us the face, the loose skin of the Abdominal wall following pregnancy and body skin following massive weight loss have been there for all to see."

(Grapp WC 1982)

Tissue expansion techniques have probably been used for centuries by other cultures for different aesthetic purposes. For Examples, women in Ethiopia and Chad have used progressive surgical placements of plates in their lips to stretch them to enormous sizes. (*Weeks 1956*)

Human tissue readily adapts to the physiologic expansion without thinning of the overlying skin. If adaptation did not occur, significant functional and aesthetic deformities would result during the individual's growth phases. Although human skin is often described as an "anisotropic elastic membrane" living integumentary tissue in vivo responds to gradual stress stimuli by increasing mitotic activity to maintain its thickness and protective integrity. In a true anisotropic state the material becomes thinner as stretching proceeds, i.e. as a rubber band reduces its diameter as it elongates. In contrast, the enlarging fetal brain stretches the calvaria at suture lines to accommodate the rapid growth of the cerebral hemispheres. Nevertheless, during puberty breast tissue responds to hormonal stimuli by slowly

enlarging the overlying skin to produce the ptotic breast mound. In pregnancy the enlarging fetus and uterus stretch the abdominal and pelvic structures over 9 months to accommodate fetal growth and facilitate parturition. All these tissues increase or maintain their thickness with growth.

(Gordon Sasaki 1998).

As early as 1905 attempts at distraction technique for bone lengthening resulted in concomitant but unrecognizable expansion of soft tissue.

(Mater 1970)

Neumann is credited with the first clinical report of a latex balloon to reconstruct an ear. He presented his findings to the American Society of Plastic and Reconstructive Surgeons in October 1956 and published "The expansion of an area of Skin by progressive distension of a subcutaneous balloon" in 1957. ***(Neumann 1957)***

He inserted a "collapsed rubber balloon" introduced beneath the skin of the side of the head in the region of the missing portion of the ear. A flexible polyethylene tube, through which the balloon could be inflated, was allowed to pass from the balloon via a subcutaneous tunnel. The tubing was exteriorized behind the ear, connected to a stopcock and filled gradually with air for 2 months. After expansion a 50% increase in the skin's surface area was achieved. At a second stage a cartilaginous graft was inserted and covered with the expanded bipedicle flap for a successful reconstruction.

(Charles G. Neumann 1973)

Radovan conceived of inserting a silicone balloon and two separate valve systems under the skin as a closed system. One valve was for filling saline and the second valve withdrew fluid. Radovan inserted his first expander in January 1976 at Georgetown University to resurface a 7x 11 cm defect on a patient's arm. This flap was expanded for only 3 weeks. A second patient had surgery 2 months later to cover an exposed fracture tibia. **(Radovan C 1976)**

The modern area of soft tissue expansion actually began following the pioneering efforts of Dr. Chedomir Radovan who converted natural observed phenomena into an application for reconstructive surgery. **(Manders et al., 1984).**

Dr. Eric Austad also presented his limited clinical experience with an osmotically driven, self inflating expander at the University of Michigan. Austad performed his first clinical cases and published with the self inflating expander in 1982. **(Austad 1982)**

Following the successful clinical application of inflatable expanders for reconstruction, efforts to comprehend the biomechanical, molecular, and light microscopic properties of expanded skin have been undertaken. These research studies have now documented biochemical changes occurring in the dermis and epidermis, including a statistically significant dermal thinning and epidermal thickening. Vascular studies have revealed a microcirculation in the capsule of expanded flaps that exceeds that of the subdermal plexus. More recent investigations have emphasized the selection of suitable animal models for the study of the skin expansion process and an elucidation of the skin's intrinsic biomechanical responses of elasticity and stress relaxation.

How quickly skin can actually be expanded, and under what conditions of pressure are current subjects of intense interest (*Slavin and Colen, 1990*).

Endoscopic expansion surgery, although recently introduced, has shown to be very beneficial. A few series are already available and document the advantages of this technique. Further improvements in the endoscopic technique associated with better instrumentation and more sophisticated devices make this approach the ideal way to perform safer expansion surgery with smaller scars and less morbidity (*Eaves III et al., 1997*).

Tissue expansion has been used in the treatment of many patients over the last 15 years at the A.V. Vishneresky Institute of Surgery, Moscow by endoscopic technique with low rate of complication than the traditional technique (*Shurobora et al., 2004*).

Actual histological changes and ultrastructural information describing tissue expansion phenomenon is still scanty in comparison to the rapid increase in clinical application.

Most of information regarding the biology of tissue expansion has been delivered from animal experiments, since human tissue is difficult to obtain.

There are sporadic data in the literature about histomorphology at expanded skin and soft tissue in the human.

(Argenta *et al.*, 1985, Grossman *et al.*, 1985).

Austad and Rose, 1982, Leighton *et al.*, 1986 and Pasky *et al.*, 1988 have published preliminary studies on expanded human tissue based on light and electron microscopical studies in experimental animals.

Epidermal Changes:

Histological examination of human expanded skin thickness revealed a significant increase in epidermal thickness after expansion than before this procedure. There appeared to be no relationship between epidermal thickness and the factors of expansion time, expander volume, location of expander, or age of the patient (Pasyk *et al.*, 1988 & Wang Y. *et al.*, 2006).

Fig (1) Thickness of the epidermis in normal and expanded skin in relation to expansion time, expander volume, location of expander and age of patients.
