صدق الله العظيم

سورة البقرة الآية: ٣٢

*First thanks to **ALLAH** to whom I relate any success in achieving any work in my life.*

*I wish to express my deepest thanks, gratitude and appreciation to **Prof. Dr. Ahmed Ibrahim Ibrahim**, Professor of Anesthesia, Intensive Care and Pain Management Faculty of Medicine, Ain Shams University for his meticulous supervision, kind guidance, valuable instructions and generous help.*

*Special thanks are due to **Dr. Mayar Hassan El Sersi**, Assist. Professor of Anesthesia, Intensive Care and Pain Management Faculty of Medicine, Ain Shams University for her sincere efforts, fruitful encouragement.*

*I am deeply thankful to **Dr. Dalia Ahmed Ibrahim**, Lecturer of Anesthesia, Intensive Care and Pain Management Faculty of Medicine, Ain Shams University for her great help, outstanding support, active participation and guidance.*

Abstract

Once it has been determined that ECMO will be initiated, the patient is anticoagulated with intravenous heparin. Cannulae are then inserted and the patient is connected to the ECMO circuit. The blood flow is increased until respiratory and hemodynamic parameters are satisfactory. Once the initial respiratory and hemodynamic goals have been achieved, blood flow is maintained, ventilator support is minimized, and vasoactive drugs are decreased to minimal levels. Frequent reassessment and adjustments are usually necessary.

The patient's readiness for weaning from ECMO should be evaluated frequently. Prior to discontinuing ECMO permanently, one or more trials should be performed during which the patient is off ECMO. Such trials give the clinician the opportunity to determine whether conventional supportive care is sufficient for the patient.

Bleeding is the most common complication (30 to 40 percent) of ECMO. Thromboembolism and cannula complications are rare.

Keywords: Pressure of oxygen in the blood - Oxygen pressure entering membrane lung - Peak inspiratory pressure - Natural lung- Left ventricle

Introduction

Extracorporeal membrane oxygenator (ECMO) is a temporary support of heart and lung function by partial cardiopulmonary bypass (up to 75% of cardiac output). It is used for patients who have reversible cardiopulmonary failure from pulmonary, cardiac or other disease. Since the first successful application of the heart-lung machine in 1953, extracorporeal technology had continued to evolve (*Gibbon, 1978*).

The ECMO consists of a cannula to drain deoxygenated blood from the patient, as well as a pump, an artificial lung to provide oxygenation, heat exchanger, and second cannula to return oxygenated blood back to the patient (*Gaffney et al., 2010*).

ECMO has been successfully used in the last 30 years to treat newborns with hypoxic respiratory failure and there is strong evidence that ECMO improves long-term survival of these infants up to 90% (*Javier et al., 2013*).

Using ECMO, it is possible to support patients for days to months while injured tissues recover. The goal of ECMO for pediatric or adult patients is to provide lung rest from the high levels of oxygen and higher airway pressures that are necessary to support oxygenation and ventilation (*Peek et al., 2009*).

ECMO can be venovenous (VV) or venoarterial (VA). During VV ECMO, blood is extracted from the vena cava or right atrium and returned to the right atrium. VV ECMO provides respiratory support, but the patient is dependent upon his or her own hemodynamics. During VA ECMO, blood is extracted from the right atrium and returned to the arterial system, bypassing the heart and lungs. VA ECMO provides both respiratory and hemodynamic support (*Wang et al., 2008*).

Aim of the work

The aim of this work is to discuss the principles and the indications of using ECMO in critically ill patients together with its potential complications.
