ACKNOWLEDGMENT

First of all, thanks to **ALLAH** whose magnificent help was the main factor in completing this work.

It is a great honour to me to express my deepest gratitude and appreciation to **Prof. Dr. Mohamed Salah El Din EL Kholy**; Professor of Pediatrics, Faculty of Medicine, Ain Shams University, for his valuable help, precious advice, continuous encouragement and constructive guidance that were the most driving forces in the initiation and progress of this work.

I wish to express my unlimited gratitude to **Prof. Dr. Heba Hassan El Sedfy**; Professor of Pediatrics, Faculty of Medicine, Ain Shams University, for her supervision, helpful discussions and suggestions. In fact, few words never suffice to do justice in thanking her for her extraordinary contribution of time, effort and valuable experience.

I can't fully express my deepest thanks to **Dr. Rasha Tarif Hamza**; Assistant Professor of Pediatrics, Faculty of Medicine, Ain Shams University, for her patience, assistance and very helpful advice and guidance during the progress of this work.

My special thanks to all my patients and their parents who agreed to share in this study. I'm thankful to them for their effort, time and cooperation.

LAILA

Introduction

Introduction

Bone densitometry is a widely used and universally accepted tool for the assessment of bone mass in adults. In the last two decades, however, interest in bone densitometry in children has increased. This can be explained first by the introduction of more effective treatment regimens aimed at increasing and maintaining bone density in a variety of diseases influencing bone development and or growth and secondly, by the fact that several reports have indicated the importance of peak bone mass in relation to future development of osteoporosis (*Van Rijn et al., 2006*).

There are 2 main reasons for measuring bone mineral content (BMC) in children: to quantify the deficits in bone mineral associated with the various disorders that cause osteopenia in children and to improve our understanding of the childhood antecedents of osteoporosis, a condition that happens to manifest itself in elderly subjects. Available data suggest that the genetic susceptibility to osteoporosis may be detectable in early childhood (*Gilsanz and Wren, 2007*).

Measurement of bone mineral density (BMD) by dual – energy x-ray absorptiometry (DEXA) is viewed widely as the preferred method for clinical use in children because of its speed, precision, safety, and wide spread availability. The radiation exposure is comparable to that received during a round trip transcontinental airplane flight (*Bachrach, 2005*).

DEXA is an attractive option for clinical use that gives estimates of bone mineral mass, fat free mass (FFM), which is approximately equivalent to lean body mass (LBM), and total fat mass (TFM). DEXA exploits the fact that the energy dependency of the strength of interaction between X-rays and bone mineral differs from that for soft tissue. At low energies, bone dominates the attenuation process while, at higher energies, X-rays interact to about the same extent with bone and soft tissue (*Sala et al., 2006*).

The 3 main limitations of DEXA measurement in children are: (1) the current lack of a standardized pediatric normative database, (2) the lack of a meaningful clinical outcome measure related to DEXA values in children, and (3) inaccuracies resulting from growth -related variations in bone and body size and composition (*Gilsanz and Wren, 2007*).

Aim of the Work

Aim of the Work

The aim of this work is to set a standardized pediatric normative database for BMD and body composition in a representative sample of healthy Egyptian male children aged 7-8 years by DEXA scanning.
