

Immunohistochemical Study of Protein Gene Product 9.5 and Single Strand DNA in Generalized and Segmental Vitiligo

Thesis

Submitted for the partial fulfillment of MD degree in
Dermatology, Venereology & Andrology

By

Mohamed Hussein Hatem Abdel Rahman Abou Hadeed
(MB. B. CH., M.Sc.)

Under supervision of

Prof. Dr. Nader Fouad Ragab

Professor of Dermatology, Venereology & Andrology
Faculty of Medicine-Ain Shams University

Prof. Dr. Nehal Mohamed Zu El-Fakkar

Professor of Dermatology, Venereology & Andrology
Faculty of Medicine-Ain Shams University

Prof. Dr. Nafissa Mohamed Amin El-Badawy

Professor of Pathology
Faculty of Medicine-Ain Shams University

Prof. Dr. Hany Mohamed Ezz El-Din El-Nazer

Professor in Dermatology, Venereology & Andrology
Research Department-National Research Center

Prof. Dr. Mahmoud Fawzy Abdel Hamid

Professor of Dermatology, Venereology & Andrology
Research Department-National Research Center

Faculty of Medicine-
Ain Shams University

2015

Acknowledgements

First I thank “God” for granting me the power to proceed and to accomplish this work,

*I would like to express my endless gratitude and appreciation to **Prof. Dr. Nader Fouad Ragab** , Professor of Dermatology, Venereology & Andrology, Faculty of Medicine-Ain Shams University, for giving me the honor of working under his supervision and providing me a lot of encouragement throughout this work and always.*

*I do appreciate the kind and active participation of **Prof. Dr. Nafissa Mohamed Amin El-Badawy**, Professor of Pathology, Faculty of Medicine-Ain Shams University.*

*I would like to acknowledge my profound gratitude to **Prof. Dr. Hany Mohamed Ezz El-Din El-Nazer**, Professor in Dermatology, Venereology & Andrology Research Department-National Research Center, for his helpful guidance and kind instructions during all the work in order to come in this form.*

*My sincere thanks to **Prof. Dr. Nehal Mohamed Zu El-Fakkar**, Assistant professor of Dermatology, Venereology & Andrology, Faculty of Medicine-Ain Shams University, for her cooperation and useful instructions.*

*Words would fail me in trying to thank **Prof. Dr. Mahmoud Fawzy Abdel Hamid**, Assistant professor of Dermatology, Venereology & Andrology Research Department-National Research Center for his detailed and constructive comments, and for his important support throughout this work,*

*I am really grateful to my **Mother, Father and Sisters** for their support and encouragement.*

A. INTRODUCTION

Vitiligo is an acquired dermatologic disorder characterized by loss of functioning melanocytes, resulting in depigmentation of the skin. (*Tobin et al., 2000; Solano et al., 2006; Van Geel et al., 2014*).

The mechanisms underlying the destruction of functioning melanocytes and the absence of melanin in vitiligo lesions remain unclear. Nevertheless, certain theories have been suggested and studied including; the genetic hypothesis, the autoimmune hypothesis, the neural hypothesis (involving neuropeptides, adrenergic and cholinergic neurotransmitters), the apoptotic theory, the viral hypothesis, the self destruction hypothesis (including the significant contribution of oxidative stress through the accumulation of H₂O₂), and convergence theory (which combines previous theories). (*Cucchi et al.,2000; Dell'Anna et al.,2003; Gauthier et al.,2003; Ortonne,2003; Hasse et al.,2004; Schallreuter et al.,2006; Solano et al.,2006*).

Developmentally, melanoblasts are derived from the neural crest, and so it is not surprising that an association between neurological disorders and changes in skin pigmentation can often be found. The segmental distribution of vitiligo, and the association of vitiligo with peripheral nerve injury, viral encephalitis, horner's syndrome and diabetic neuropathy, supports the neurological theory in vitiligo (*Al'Abadie et al.,1994; Liu et al.,1999*).

Protein gene product 9.5 (PGP 9.5) is a general marker for all cutaneous sensory and autonomic nerve fibers. It has been studied in skin biopsies of various dermatologic disorders (*McArthur et al.,1998; Omdal et al.,2002; Antunes et al.,2003; Ebnezer and Daniel,2004*).

Studies of PGP 9.5 in vitiligo have been performed. One study showed a minimal increase in PGP 9.5 positive nerve fibers at the dermoepidermal junction and lower malpighian layers in patients with vitiligo at the periphery of the lesion relative to normal skin

(*Al'Abadie et al.,1994*). Other reported no difference in PGP 9.5 positive nerve fibers between lesional, nonlesional, and normal skin in patients with vitiligo (*Liu et al.,1999*). However, recently *Aroni et al.,2008* detected a statistically significant difference in the number of PGP 9.5-positive nerve fibers/axons in the papillary dermis between the centre and periphery of the lesions of vitiligo (i.e. increased at the center in comparison with the periphery).

A few controversial theories have been studied concerning the role of apoptosis in vitiligo. The lack of evidence for the involvement of this process has been reported in several studies (*Tobin et al.,2000; Van den Wijngaard et al.,2000a*). However vitiligo as a manifestation of apoptosis is supported by its histopathological findings, and is particularly evident from the changes at the border between the depigmented and clinically normal (uninvolved) skin (*Kovarik et al., 2009*).

A monoclonal immunoglobulin M (IgM) antibody was used by *Aroni et al., 2008* against single strand DNA (ssDNA), which specifically stains the apoptotic cells and has been applied in vitiligo to differentiate between apoptotic and necrotic cells.

On the basis of dermal PGP 9.5-positive nerve fibers and ssDNA-positive (apoptotic) cells, *Aroni et al.,2008* concluded that there is a relationship between the autonomic nerve system function and apoptosis, supporting the hypothesis that the destruction of functioning melanocytes in vitiligo could be the end result of different interacting pathogenic mechanism, such as apoptosis and accumulation of neural fibers/axons.

B. AIM OF THE WORK

The aim of this work is to study the possible contribution of either the neural mechanism or apoptotic mechanism or both together in the etiopathogenesis of generalized and segmental vitiligo variants. This was done through immunohistochemical study of PGP9.5 as evidence of neural mechanism and ssDNA as an evidence of apoptotic mechanism in vitiligo.
