**A study on the relation between maternal blood level of
some metals and birth weight using LIBS technique**

By

Jehan Mohamed Abdel Rahman Al Sharnoubi

**Thesis Submitted in partial fulfillment of the requirements of
PhD degree in medical laser applications in Pediatrics**

**Department of Medical Applications of Lasers (MAL)
National Institute of laser Enhanced Science (NILES)
Cairo University
2008**

Supervisors

**Title: A study on the relation between maternal blood level
of some metals and birth weight using LIBS**

Name: Jehan M.A. Alsharnoubi

This thesis for the degree of PhD had been approved by:

Professor Dr. Ekram Abdel Salam Ahmed
Professor of pediatrics & Genetics
Faculty of Medicine
Cairo University

Professor Mohamed Abdel Harith Mohamed
Professor of laser physics
National Institute of Enhanced Laser Science
Cairo University

Dr. Mohamed Amr Elnoury
Professor of Gynecology & Obstetrics
National Institute of Enhanced Laser Science
Cairo University

Cairo University
2008

List of Tables

Table (1): Experimental set up components for LIBS.....	78
Table (2a): Comparison between the clinical characteristics of the newborns in both groups of the study	81
Table (2b,1): Comparison between metal intensities of the newborn in both groups	82
Table (2b,2): Comparison between metal intensities of the mothers in both groups	82
Table (3a): Comparison between clinical characteristics of the newborns in group I(NBW) according to living area (polluted or non polluted).....	83
Table (3b,1): Comparison between metal intensities of the newborns in group I (NBW) according to living area (polluted or non polluted areas).....	84
Table (3b,2): Comparison between metal intensities of the mothers in group I (NBW) according to living area (polluted or non polluted areas).....	84
Table(4a): Comparison between clinical characteristics of the newborns in group II (LBW) according to living area (polluted or non polluted).....	85
Table (4b,1): Comparison between metal intensities of the newborns in group II(LBW) according to living area (polluted or non polluted).....	86

Table (4b,2): Comparison between metal intensities of the mothers in group II(LBW) according to living area (polluted or non polluted).....	87
Table (5a): Comparison between the clinical characteristic of the newborns in both groups living only in polluted areas.....	88
Table (5b,1): Comparison between metal intensities of the newborns in both groups living only in polluted areas.....	89
Table (5b,2): Comparison between metal intensities of the mothers in both groups living only in polluted areas.....	90
Table (6a): Comparison between clinical characteristics of the newborns in group I (NBW) born to smoking or non smoking fathers.....	91
Table (6b,1): Comparison between metal intensities of the newborns in group I (NBW) born to smoking or non smoking fathers.....	92
Table (6b,2): Comparison between metal intensities of the mothers in group I (NBW) born to smoking or non smoking fathers.....	92
Table (7a): Comparison between clinical characteristics of the newborns in group II (LBW) born to smoking or non smoking fathers.....	93
Table (7b,1): Comparison between metal intensities of the newborns in group II (LBW) born to smoking or non smoking fathers.....	94
Table (7b,2): Comparison between metal intensities of the mothers in group II (LBW) married to smoking or non smoking fathers.....	95
Table (8a): Comparison between the clinical characteristic the newborns, born to smoking fathers from both groups.....	96
Table (8b,1): Comparison between metal intensities of the newborns, born to smoking fathers from both groups.....	97

Table (8b,2): Comparison between metal intensities of the mothers married to smoking fathers from both groups.....	98
Table (9): The significance of differences between correlation coefficients between weight and head circumference and metal intensities of the mother and her baby in both groups	101
Table (10): The significance of differences between correlation coefficients between length and head circumference and metal intensities of the mother and her baby in both groups	103
Table (11): The significance of differences between correlation coefficients between head circumference and metal intensities of mother and her baby in both groups.....	105
Table (12): The significance of differences between correlation coefficients between metal intensities of the baby and his mother in both groups.....	108
Table (13): The significance of differences between correlation coefficients between metal intensities of the mother and her baby in both groups.....	110

ACKNOWLEDGMENT

First and foremost thanks to God, whose kindness and mercy helped me throughout this work.

I would like to express my profound appreciation and gratitude to the guidance, follow up, fruitful remarks, patience and encouragement of Professor Dr. ***Ekram Abdel-Salam***, Professor of Pediatrics and Genetics, Faculty of Medicine, Cairo University, who without her I would have never accomplished this work. This thesis was exalted by being under her supervision.

My deepest appreciation and gratitude to Professor Dr. ***Mohamed Abdel Harith***, Professor of Laser Physics, National Institute of Laser Enhanced Science, Cairo University, for his help, supervision, guidance, follow up and fruitful advice.

I am grateful to Professor Dr. ***Mohamed Amr Hussein Elnoury***, Professor of Gynecology & Obstetrics, National Institute of Laser Enhanced Science, Cairo University, for his effort, support and much assistance during preparation of this thesis and collecting data for the study.

My thanks are extended to the staff members and colleagues working and responsible of the LIBS laboratory of the National Institute of Laser Enhanced Science, Cairo University under supervision of Professor Dr. M. Abdel Harith.

Last but not least I am indebted to those patients who participated in this work, by donating their blood and I pray God to give them an everlasting cure.

1. Introduction

1.1-Introduction and Aim of Work

The placenta serves as the point of contact between maternal and fetal circulation. It functions as the means by which all necessary nutrients are delivered to the fetus, as well as a barrier to prevent passage of toxic substances, including metals. If the latter is accomplished by binding of the metals to the placenta, it may interfere with placental function, in particular the transport of essential trace elements required for fetal growth and development. The exposure of pregnant women to toxic metals and transfer from the mother's blood to the developing fetus has mostly been studied in heavily exposed individuals. There are few studies on placental concentrations of toxic metals in women living in less polluted areas, and for some metals the reported data are conflicting (*WHO 1996*).

The fetus is totally dependent upon the mother for his supply of minerals essential for growth and development. The placental transport of minerals is highly complex and is determined by maternal, fetal, and placental factors that is specific for each element (*Lall and Wapnir, 2005*).

Maternal nutrition before and during pregnancy may influence the course of the pregnancy, fetal development and the child's health in its early and also adult life. Maternal underweight before pregnancy (BMI<19.8

kg/m²) and low pregnancy weight gain may increase the risk of low infant birth weight (*Szostak-Wegierek, 2000*).

Fetal under nutrition represents a large numbers of newborns in developing countries, with adverse consequences for their immediate survival and lifelong health. It manifests as intrauterine growth retardation (IUGR), defined as birth weight <10th percentile, which probably underestimates the number failing to achieve full growth potential. Birth weight is a crude measure of the dynamic process of fetal growth and does not capture effects of fetal under nutrition on body composition and the development of specific tissues. The link between maternal nutrition and fetal nutrition is indirect. The fetus is nourished by a complex supply line that includes the mother's diet and absorption, endocrine status and metabolism, cardiovascular adaptations to pregnancy and placental function (*Fall, et.al, 2003*).

Low birth weight newborns (LBW) are weighing 2500 g or less at birth. LBW are associated with increased neonatal morbidity and mortality. Neonates weighing less than 1500 g are termed as very low birth weight newborns (VLBW) and they are associated with neonatal deaths and handicapped newborns. Newborns of extremely low birth weight (ELBW) are less than 1000 g and mostly die (*Sommerfelt, 1998*).

Small for gestational age (SGA) babies are those whose birth weight lies below the 10th percentile for that gestational age. They have usually been the subject of intrauterine growth restriction (IUGR), formerly known as intrauterine growth retardation. Low birth weight (LBW), is sometimes used synonymously with SGA, or is otherwise defined as a fetus that weighs
