ABSTRACT

Objective: To assess the role of high resolution sonography and interventional sonography in diagnosis and management of diabetic hand tendinopathy.

Methods: One hundred and two consecutive diabetic patients, along with 40 normal controls without a known history of diabetes were examined in the study. Of the diabetic patients, 54 females & 48 males, mean age years = 53.82 ± 9.7 yrs, 91 had NIDDM and 11 had IDDM. All patients were subjected to clinical examination to assess the presence of diabetic cheiroarthropathy(DCA) by measuring the angle of extension at the PIPJ using a goniometer, examined for trigger fingers(TF), tendon nodules, thickened indurated skin over the dorsum of the hand & for Tinel's sign. High-resolution ultrasonography was used to examine the digital flexor tendons, as well as, their synovial & fibrous sheaths, median nerve and skin thickness. In this study, 34 patients with DCA and/or TF were subjected to injection of their flexor tendon sheaths, using a mixture of corticosteroid & local anesthetic; 68 patients were injected blindly while the other 11 patients were injected under ultrasound guidance. A time series design was employed in which individual patients served as their own control before and after injection.

Results: Our patients were classified into three groups; group A with DCA, group B with TF and group C with neither DCA nor TF. Cheiroarthropathy was found in 24/102 patients(24%). Diabetic patients with cheiroarthropathy had significantly increased frequency of retinopathy (88% versus 4%), nephropathy (88% vs 4%), and peripheral neuropathy (42% vs 12%) and were more often on insulin treatment(20% vs 17%). They showed significantly increased synovial sheath thickness on ultrasonography (1.1 ± 0.19 mm vs 0.72 ± 0.12 mm in the diabetic patients without DCA, versus 0.28 ± 0.1 mm in the control group). Trigger finger was found in 11/102 patients (11%). Diabetic patients with TF had significantly increased frequency of retinopathy (37% vs 4%), nephropathy (37% vs 4%), and peripheral neuropathy(42% vs 12%) and were more often on insulin treatment(44% vs 17%). They showed significantly increased A1 pulley thickness on ultrasonography (1.17 ± 0.19 mm vs 0.77 ± 0.1 mm in the diabetic patients without trigger finger). No differences in the tendon itself could be detected between the different groups(A, B & C groups). Diabetic patients with DCA and/or TF (group A & B) had increased frequency of CTS, sclerodactyly & lower extremity ischemia, compared with group C but these differences were also statistically insignificant. In patients with clinical evidences of carpal tunnel syndrome (CTS), the mean median nerve cross-sectional area was 1.4 ± 0.42 mm², compared to 0.4 ± 0.2 mm² in patients without clinical evidences of CTS. Ultrasonography of the median nerve showed significant caliber change across the carpal tunnel and/or cross-sectional area > 1.0 mm² in 92%(87/117) of these patients with clinical evidences of CTS. Response rate to corticosteroid injection, defined as complete resolution of the abnormal diabetic finger after injection were 24/34 (71%) at one month post-injection, which is significantly different from pre-injection (P value < 0.001). Response rate for trigger finger injection alone was 29/32 (91%) & response rate for DCA injection alone was 0/0 (0%). Response rate for ultrasound-guided injection was 94%(17/18) while response rate for blind injection was 90%(18/20).

Conclusion: Diabetes-associated hand conditions including diabetic cheiroarthropathy, trigger finger, diabetic sclerodactyly & carpal tunnel syndrome are common in Egyptian diabetic patients and commonly associated with diabetic microvascular complications (namely; retinopathy, nephropathy and peripheral neuropathy) as well as, lower extremity ischemia. High resolution ultrasonography is the modality of first choice for assessment of DCA, TF, CTS and sclerodactyly, being easy, rapid, inexpensive, widely available and accurate. Corticosteroid injection is an effective safe underused therapy for diabetic hand conditions and should be considered in all patients with DCA and/or TF while surgery should be considered only after repeated failure of corticosteroid injection.

Key word

Diabetes mellitus- limited joint mobility- diabetic cheiroarthropathy- contracture- tenosynovitis- trigger finger-hand, high resolution ultrasonography.

Acknowledgement

First and foremost, I feel indebted to Allah, the kind and merciful.

I would like to express my sincere appreciation and deepest gratitude to Prof. Dr./ Sahar Mostafa Al-Mashad, professor of Radiodiagnosis, faculty of medicine, Cairo university, for her supervision, constructive criticism and generous support throughout every step of this work. It has been a great pleasure for me to proceed with this work under her kind supervision.

I'm particularly and greatly obliged to Prof. Dr./ Khaled Tahseen Al-Hadidi, professor of Rheumatology and rehabilitation, faculty of medicine, Cairo university, for all his help and support without which, this work couldn't have been achieved. I would like to express my sincere thanks and appreciation to him for his thorough clinical assessment of the patients, injection of the patients and for his invaluable suggestions, creative advice and criticism.

My profound thanks are due to Prof. Dr./ Reda Saad Abd Al-Lateef, Assist prof. of Radiodiagnosis, faculty of medicine, Cairo university, as this work wouldn't come to light without his endless effort, continuous encouragement, creative advices and fruitful guidance.

No words can fulfill the feeling of gratefulness and respect I carry to Prof. Dr./ Mahmoud Abd-Alla Sharaf, Chairman of the radiology department, faculty of medicine, Cairo university, for his endless support, continuous encouragement and for his sincere fatherly attitude. His guidance and advice will always be fingerprinted on my heart and soul.

I would like to thank all my professors, the senior staff and all my colleagues, without their help, support and cooperation, this work couldn't have been completed.

I would like to thank all the staff of the diabetic outpatient clinic of the faculty of medicine, Cairo university, for their help, support and cooperation.

Lastly, I would like to thank the patients who participated in this work, the backbone of this study, who despite their pains, showed a great pure spirit of bravery and cooperation.

Title: Role of High Resolution Sonography and Interventional Sonography in Diagnosis and Management of Diabetic Hand Tendinopathy.

Investigator: Abo El-Magd Mohamed El-Bohy, M.Sc..

Supervisor: Prof. Dr./ Khaled Tahseen El-Hadidi

Assist. Prof. Dr./ Reda Saad Abd Al-Lateef

Principal Supervisor: Prof. Dr./ Sahar Mostafa El-Mashad

Rational and Background::

Diabetes mellitus leads to structural changes in tendons that were detected by electron microscopic studies in the form of increasing packing density of collagen fibrils and decreasing fibrillar diameter, with abnormal fibrillar morphology showing foci of twisted, curved, overlapping, highly disorganized collagen fibrils due to non-enzymatic glycation of collagen over many years. These changes lead to tightening and consequent shortening of the tendons; the short Achilles tendon is an example (*Grant et al.*, □□□□).

Carpal tunnel syndrome, Dupuytren's contracture, flexor tenosynovitis, trigger finger and limited joint mobility syndrome are more prevalent in diabetic patients than in the general population. These changes have higher incidence in IDDM than in NIDDM with positive correlation with increasing age of the patient, increasing

duration of DM and with the presence of microangiopathy (*Gamstedt et al.*, □□□□).

Infective tenosynovitis is common in diabetic patients and needs early diagnosis, followed by surgical treatment, sheath irrigation and appropriate antibiotic (*Gonzalez*, □□□□).

High resolution sonography is currently the only real-time cross-sectional imaging technique for tendons. It is the direct competitor of MRI, since sonograms can be quickly obtained in virtually any plane with exquisite spatial and contrast resolution, in addition to short examination time, low cost and lack of ionizing radiation making it ideal as a screening tool (*Gibbon & Wakefield*, □□□□ *and Fornage*, □□□□).

Sonographically, all tendons are echogenic with characteristic fibrillar echotexture on longitudinal scans. Tendon tears are diagnosed if there is partial or complete interruption of fibers. In tendinitis, the tendon is thickened, hypoechoic with blurred margin and distended synovial sheath by hypoechoic fluid in acute tenosynovitis and diffuse hypoechoic synovial thickening in chronic tenosynovitis (*Neuhold et al.*, □□□□ *and Fornage*, □□□□).

Power Doppler sonography plays a pivotal role in the diagnosis and follow up of tendinitis, tenosynovitis and peritendinitis. Objective quantification of hypervascularity by power Doppler sonography permits
