Abstract

In recent years the biotechnological production of bulk biopolymer has focused on the synthesis of biodegradable polymers to replace their non-biodegradable counterparts derived from fossil resources. The microbial production of polyhydroxybutyrate (PHB) is a complex process in which the final quality and quantity of PHB depends on large number of process operating variables consequently the design and optimal operation of microbial process for efficient PHB production is an extremely interesting problem.

In trend toward suitable manufacturing bioplastic, that can be produced from renewable resources have attracted great attention. The present study investigates how key process operating variables affect biomass production rate and PHB accumulation in cells.

The obtained data reports that, bacterial strain which identified as *Bacillus cereus* capable of PHB production in medium containing glucose, tryptone, NaCl and yeast extract in submerged culture at 37 °C, pH 6 for 48 hrs and the yield is approximately about 70% of cell dry weight. In addition, molasses is considered as the suitable and relatively cheap carbon feed-stocks have to be identified to maximize cost-effective production of PHB.

Acknowledgement

Glory is to God, who has bestowed man with wisdom and intellect.

I would like to express my deep appreciation and gratitude to **Prof. Dr. Fahmy T. Ali**, Professor of Biochemistry, Faculty of Science, Ain Shams University, for suggesting the subject, his active supervision, moral help, great effort, patience, meticulous observation, continuous encouragement and generous advice during this work.

I would like also to express deepest thanks to **Dr. Sherif M. Keshk**, Assistant Professor of Chemistry, Institute of Environmental Studies and Research, Ain Shams University, for his valuable supervision, sincere guidance, sage advice, insightful criticisms and wholehearted support throughout this work.

I am grateful to **Dr. Usama A. Abd Ellatif**, Lecturer of Biochemistry, Faculty of Science, Ain Shams University, for his tutorial guidance, valuable assistance and efforts.

Also, deep thanks to my Professors, and Colleagues in the Biochemistry Department, Faculty of Science, Ain Shams University, for their unfailing support and encouragement.

Last, but not least, my family for unfailing support and encouragement.

Marwa Mohsen Mostafa Sarhan

INTRODUCTION

Biotransformations are the basis of life. All natural organic and most inorganic molecules, the building blocks of organic and living matter, are subject to constant change and turnover. The turnover time is determined by the reactivity and the reaction partners of the respective compounds, and varies from millions of years to microseconds (*Nishino et al., 2010*).

Biotransformation differs from biosynthesis where complex products are assembled from simple substrates by whole cells, organs or organisms. They are also different from biodegradations in which complex substances are broken down to simple ones. It has great potential to generate novel products or to produce known products more efficiently (*Archana et al., 2001*).

Biotransformation capabilities of microorganisms and their enzymes for the production of a wide variety of fine chemicals are well known (*Ward and Singh, 2000*).

Nowadays management of plastic waste is a major worldwide concern. As a synthetic plastic is non-

biodegradable, it is creating a great havoc to environment. Plastic and synthetic polymers are mainly produced using petrochemical material and they contribute to environmental pollution. They are also dangerous to number of animal species (*Flora et al., 2010*).

Although plastic has many advantages its non-biodegradability is a major drawback, which forced us to think upon a material which can replace plastic. Earlier studies showed that Polyhydroxybutyrate (PHB) is biodegradable material, which has physical properties similar to the synthetic plastic. PHB has various applications in different areas like medicine, drug manufacture, agriculture and various industrial purposes. Some of the major applications of PHB are in drug delivery in developing medical sutures, bone marrow scaffold, tissue engineering devices and agriculture products (*Sarika et al., 2008*).

PHB is equivalent to a very basic polymer, polyhydroxyalkanoates (PHA). PHB is produced by microorganisms in the form of reserved food granules under stress condition like excess availability of carbon source but
