Abstract

We studied 200 patients destined to have ICSI cycles either for the first time or repeatedly in the kasralainy IVF unit. They have done ICSI cycles due to male factor, ovarian, tubal, uterine factors or unexplained infertility.

All patients had routine office hysteroscopy prior to their cycles assessing the vagina cervix, isthmus and uterine cavity and If laparoscopy was indicated as in cases with endometriosis, endometriomas, excision of an ovarian cyst or salpingectomy in cases with hydrosalpinx, it was done to the patient. The additive diagnostic and therapeutic values of hysteroscopy and laparoscopy were estimated and compared to the diagnostic value of the routinely used modalities as transvaginal U/S and HSG. The comparison revealed marked superiority of the office hysteroscopy in its diagnostic power over the transvaginal U/S and HSG especially in assessing uterine intracavitary lesions, This is added to its therapeutic contribution which can be done in the same setting

Acknowledgment

First of all, I wish to express my sincere thanks to God for his care and generosity throughout of my life.

*I would like to express my sincere appreciation and my deep gratitude to **Prof. Dr.HISHAM BADAWY** Professor of Obstetrics and Gynecology, Faculty of Medicine, Cairo University, who assigned the work.*

*I would like to express my great thanks to **Dr.AKMAL NABIL ELMAZNY** Ass. Professor of Obstetrics and Gynecology, faculty of medicine, Cairo University for her great support throughout the whole work.*

*I am also deeply indebted to **Dr. WALEED SABER**, Lecturer of Obstetrics and Gynecology of, faculty of medicine, Cairo University, for her great support throughout the whole work as well for the tremendous effort he has done in the meticulous revision of this work.*

At last, I am indebted for family and friends for their great support, patience and continuous encouragement.

Mostafa Mahmoud Ragai

INTRODUCTION

Introduction

Despite advances in the field of assisted reproductive techniques (ART), only one-third of cycles started end in a pregnancy and one-fourth result in a live birth (**Society for Assisted Reproductive Technology , 2007**).

ART has developed over a decade to become useful for couples with infertility which cannot be cured by simple treatments. The birth rates are comparable to natural conception and the incidence of congenital malformations is not increased. The costs and complexities of treatment have been reduced, which in turn has reduced the stress and social inconvenience of therapy. Problems related to the birth risk of multiple pregnancy and the use of the stimulated cycle are being reduced as new techniques for severe male infertility and the detection of genetic abnormalities in the embryo have been introduced(**Society for Assisted Reproductive Technology , 2007**).

Intrauterine pathologies are found to be present in 25% of infertile patients (**Levi Setti PE.et al., 2004**) Structural abnormalities of the uterine endometrial cavity may affect the reproductive outcome adversely, by interfering with the implantation or causing spontaneous abortion. Therefore, exclusion of any intrauterine pathology becomes an important step before subjecting the patient to ART. Intrauterine abnormalities may be visualized using variety of techniques, including hysterosalpingography (HSG), transvaginal sonography (TVS)/sonohysterography (SHG), and hysteroscopy (**Devroey P. et al., 2009**).

The HSG, although very sensitive (98%), has low specificity (34.9%), a positive predictive value (PPV) of 69.9%, and a negative predictive value (NPV) of 92% (**Preuthipan S. et al., 2003**). The TVS is more specific (96.3%) and sensitive (100%) than HSG, with a 91.3% PPV and a 100% NPV (**Shalev J et al., 2000**). Although hysteroscopy is considered the “gold standard,” controversies still exist between TVS and hysteroscopy in the diagnosis of intrauterine abnormalities.

With the invention of the miniature hysteroscope, it is possible to perform hysteroscopy in an office setting for diagnostic indications and certain therapeutic interventions (**Bettocchi S. et al., 2004**).

Although operative hysteroscopy has progressively been accepted for the treatment of intrauterine pathologies, diagnostic hysteroscopy is still not widely and routinely used. Whereas almost all urologists utilize office cystoscopy to evaluate bladder pathology, it is estimated that less than 20% of gynecologists utilize office hysteroscopy to evaluate uterine pathology (**Isaacson, 2002**).

Office diagnostic hysteroscopy is also indicated for the evaluation of the cervical and uterine factors in patients with infertility and especially in those who are scheduled to enter an in vitro fertilization (IVF) program. (**Bettocchi S. et al., 2004**).

Diagnostic laparoscopy is indicated mainly for investigation of pelvic pain and subfertility (**Keye WR. Et al., 1996**), as well as it is the standard method for the diagnosis of endometriosis and adhesions, as no

other imaging technique provides the same degree of sensitivity and specificity. **(Munro Malcolm G. et al., 2007).**

Laparoscopic operations for the treatment of mechanical infertility are probably equally effective to similar procedures performed by laparotomy. In patients with extensive adhesions, however, the effectiveness of all procedures is limited. Assisted reproductive technologies such as in vitro fertilization and embryo transfer are necessary in these situations. **(Gomel V et al., 1995)**

In the present study we have evaluated intrauterine pathologies using Transvaginal Ultrasound (TVS), Hystero-Salpingography (HSG) and outpatient (office) hysteroscopy (OH) in patients scheduled for ART—IVF or intracytoplasmic sperm injection (ICSI)—ET. Our objectives were to evaluate the importance of subjecting the patient to OH before ART and the value of Diagnostic Office Hysteroscopy on ICSI outcome comparing to TVS, HSG. Also we tried to assess the diagnostic and therapeutic values of laparoscopy in such patients.
