

**STUDY OF ENDOSCOPIC UPPER GIT  
LESIONS IN EGYPTIAN PATIENTS WITH  
CHRONIC LIVER DISEASE DUE TO EITHER  
HCV INFECTION OR SCHISTOSOMIASIS**

Thesis

Submitted for partial fulfillment of  
Master degree in Tropical Medicine

Presented by  
**Mohammad Ibrahim EL Far**  
M.B., B.CH

Under Supervision of  
**Prof. Dr. Salah Saif El Din**  
Professor of Tropical Medicine  
Faculty of Medicine  
Ain Shams University

**Prof. Dr. Mohammad Amin Sakr**  
Professor of Tropical Medicine  
Faculty of Medicine  
Ain Shams University

**Brig.Dr. Medhat Hassan EL Sahhar**  
M.D Tropical Medicine  
Head of Hepatology&Gastroentrology  
Department –Police Hospital - Agouza

**Faculty of Medicine**  
**Ain Shams University**

٢٠٠٨

بِسْمِ اللَّهِ الرَّحْمَنِ الرَّحِيمِ

يَرْفَعِ اللَّهُ الَّذِينَ آمَنُوا مِنْكُمْ وَالَّذِينَ أُوتُوا  
الْعِلْمَ دَرَجَاتٍ وَاللَّهُ بِمَا تَعْمَلُونَ خَبِيرٌ

صدق الله العظيم

سورة المجادلة

## Acknowledgment

*Thanks to All mighty **GOD** from the beginning till the end for always providing me with a helping hand and putting me on the right track all through the way.*

*My deepest thanks to Professor Dr Salah Saif El Din, professor of Tropical medicine, Faculty of Medicine, Ain Shams University to whom I am in debt and who cared about every detail written down in this work. It was impossible for me to finish this work without his wise instructions, his deep clear ideas, which were inspiring, his guidance and his way of thinking. Thanks for always being willing to help. Thanks for his encouraging advices. No words would fulfill my deepest gratitude towards his support.*

*Special thanks to Professor Dr Mohamad Amin Sakr, professor of tropical medicine, Faculty of Medicine, Ain Shams University who helped me to achieve my goal in this work. Thanks for his support and sincere guidance, supervision and advices. He was always willing to give his time without any delay. Thanks for the inspiration he offers that guided me through many steps till we reached the target. I shall never forget his guidance and support through out the whole work.*

*Many thanks to Dr Medhat Hassan El-Sahhar, consultant and head of the Hepatology, Gastroenterology and Endoscopy Department, Police Authority Hospital, from whom I have learned a lot. Thanks for his guidance, supervision, advices, his creative personality and understanding mind. I would like to express my deepest feelings of gratitude towards him for helping me through this study.*

*Thanks for my family and my fiancée who were of great help, gave me lots of guidance and support.*

Mohamed Ibrahim El Far

## INTRODUCTION

Endemic chronic liver disease is a special situation present in Egypt in which schistosomiasis, virus C infection, or both combined are the main etiological factors.

The prevalence of HCV antibodies increases from 2.7% in those <20 years of age to more than 40% in males aged 40-50 years. The peak in HCV prevalence in the 40-50 year age group corresponds to the aging of the cohort of children infected through schistosomiasis treated parentally in the 1960s-70s (accounting for 12.4% of all HCV infections observed today among adults). Following this initial founding event, the HCV spread in the community through iatrogenic factors, and particularly injections (37.9% of the overall attributable fraction in adults). In children, however, no iatrogenic factors were associated with increased risk of infection, suggesting a change in the pattern of HCV spread (*Arafa, 2009*).

HCV may cause very little detected illness in young adult Egyptians. However, cirrhosis can be the end stage of chronic liver disease (*Dagher, 2001*). At least two thirds of cirrhotic patients develop esophageal varices during their lifetime. Severe upper gastrointestinal (UGI) bleeding as a complication of portal hypertension develops in about 30%-40% of cirrhotics (*Jensen, 2002*).

Esophageal and gastric varices are common manifestations of advanced chronic liver disease, but other endoscopic gastrointestinal manifestations of portal hypertension may occur. In the upper gastrointestinal tract, portal hypertensive gastropathy, particularly when severe, and gastric antral vascular ectasias are important alternative causes of gastrointestinal bleeding.

Endoscopy can assess the presence and size of gastroesophageal varices, the appearance of the variceal wall, and the presence and severity of portal hypertensive gastropathy (*Escorsell, 2001*). It has greatly facilitated the management of some patients with chronic liver disease. Upper endoscopy plays a pivotal role in the diagnosis and management of oesophageal and gastric varices (*Lau, 1991*). It is used for the prophylaxis of the first bleeding episode, therapy of active bleeding and prophylaxis of recurrent bleeding (*Biecker, 2002*).

The portal hypertensive gastropathy (PHG) and duodenopathy (PHD) define a wide spectrum of diffuse macroscopic lesions that appear in the gastric mucosa of patients with portal hypertension (*Elnaser, 2002*).

Gastroduodenal ulcers and gastroduodenal erosions are particularly frequent in cirrhotic patients and are significantly related to hypertensive gastropathy (*Auroux, 2003*).

Although HCV and schistosomiasis lead to chronic liver disease and portal hypertention, yet the last complications may differ according to the aetiology. Schistosomiasis is a mesenchymal lesion leading mainly to periportal fibrosis and the insult is mainly around the portal vessels. On the other hand HCV causes parenchymal insult which leads to portal hypertention. Although both aetiology, lead at the end to portal hypertention, it is suspected that the manifestations of portal hypertention and the prognosis of the disease are different.

## **AIM OF THE WORK**

The aim of this work is to screen the endoscopic upper GIT lesions in patients with chronic liver disease caused by either HCV or schistosomiasis, in a trial to evaluate the impact of each disease separately.

## **HEPATITIS C HISTORY and EPIDEMIOLOGY**

The history of hepatitis C began a little more than 2 decades ago, when researchers transmitted non-A, non-B hepatitis from patients with transfusion-associated hepatitis to chimpanzees, demonstrating that the disease resulted from a transmissible agent. A major break-through came in 1989 with the cloning of the hepatitis C virus (HCV) (*Zein, 2002*).

In the first years after the discovery of HCV, its primary role in post-transfusion hepatitis and its tendency to induce persistent infection after exposure were widely documented. These early years generated considerable debate about whether HCV was associated with significant morbidity or mortality in infected patients. Compelling evidence, however, linked HCV infection to liver failure and hepatocellular carcinoma (HCC) and was followed by a series of well-designed studies that suggested an increase in liver-related mortality among patients with chronic HCV infection (*Seeff, 2002*).

We now firmly recognize that HCV infection is associated with substantial morbidity and mortality and that it clearly represents a global health challenge. Chronic hepatitis C (HCV) infection is typically characterised by slowly progressive hepatic fibrosis, with progression from

stage 1 (no fibrosis) to stage 4 (cirrhosis) taking place approximately 10-15 fibrosis units (median) per decade. However, it is recognised that some patients do not progress while others rapidly develop significant fibrosis (*Zein 2003*).

Hepatitis C virus (HCV) infects over 150 million individuals worldwide. Chronic hepatitis C also represents an important public health threat and economic burden because it is responsible for a high incidence of cirrhosis and hepatocellular carcinoma and accounts for approximately 30% of all patients undergoing liver transplantation (*Pawlotsky et al., 2004*).

Hepatitis C virus (HCV) was well adapted to emerge worldwide in the late 20<sup>th</sup> century. Transmitted primarily through percutaneous routes, it took advantage of two emerging epidemics: an epidemic of recreational injection drug use in industrialized countries and an epidemic of unsafe injections primarily in developing countries, made possible by the expanded use of parenteral therapeutics and declining injection equipment prices after the World War II. The result at the beginning of the 21<sup>st</sup> century is a large pool of HCV-infected people, many of whom have asymptomatic, slowly progressing liver disease.

The greatest burden from HCV infection will come from the long-term complications of this chronic liver disease, namely cirrhosis and hepatocellular carcinoma,

---

which in any individual may take decades to develop. Whether increases in HCV infections in the 21<sup>st</sup> century will lead to increases in HCV-related complications in the 21<sup>st</sup> will depend on three factors: the number of people currently infected with the virus, the stage of disease in these individuals, and the natural history of HCV infection (*Alter 2002*).

Data from natural history studies suggest that progression to cirrhosis is much slower in people infected as children or young adults, of whom fewer than 5% have progressed to cirrhosis in the first 20 years, than in people infected as older adults, of whom 10-20% have progressed to cirrhosis in the first 20 years. Beyond 20 years there are few data on what to expect and no data to suggest whether disease progression will accelerate or decelerate. In addition, co-morbidities such as alcohol use and human immunodeficiency virus may substantially alter the natural history of chronic hepatitis C (*Seeff, 2002*).

In Egypt, where unsafe injection practices during a disease eradication programme may have inadvertently lead to the largest known epidemic of HCV infection, the current prevalence of infection correlates with what would be expected if incidence of infection had increased in the
